NORTH CAROLINA UTILITIES COMMISSION

1 P R O C E E D I N G S

2 CHAIR MITCHELL: All right. Good
3 afternoon. Let's go on the record, please. I'm
4 Charlotte Mitchell, Chair of the Utilities
5 Commission and with me are the following
6 Commissioners. When I call your name, please
7 announce your presence. Commissioner Brown-Bland?

8 COMMISSIONER BROWN-BLAND: Present.

9 CHAIR MITCHELL: Commissioner Clodfelter?

10 COMMISSIONER CLODFELTER: Yes, good
11 afternoon.

12 CHAIR MITCHELL: Commissioner Duffley?

13 COMMISSIONER DUFFLEY: I'm present.

14 CHAIR MITCHELL: Commissioner Hughes?

15 COMMISSIONER HUGHES: Here.

16 CHAIR MITCHELL: Commissioner McKissick?

17 COMMISSIONER MCKISSICK: Present.

18 CHAIR MITCHELL: And Commissioner
19 Kemerait?

20 COMMISSIONER KEMERAIT: Present.

21 CHAIR MITCHELL: I now call to order
22 Docket Number E-2, Sub 1300, which is captioned In
23 the Matter of Duke Energy Progress, LLC's, Request
24 to Initiate Technical Conference Regarding the

NORTH CAROLINA UTILITIES COMMISSION

1 Projected Transmission and Distribution Projects to
2 be Included in a Performance-Based Rate-Making
3 Application.

4 North Carolina General Statute § 62-133.16
5 authorizes performance-based regulation or PBR for
6 electric public utilities. Pursuant to statutory
7 directive on February 10th, 2022 Commissioner issued
8 an order adopting Commission Rule R1-17B which
9 implements this statute.

10 On June 8th, 2022 Duke Energy Progress,
11 LLC or DEP filed a letter with Commissioner
12 indicating it's intent to file a Notice of Intent to
13 File General Rate Application that includes
14 performance-based regulation application as
15 authorized under North Carolina General Statute
16 § 62-133.16 with a PBR Application targeted for
17 filing no earlier than October 6, 2022.

18 DEP also requested pursuant to Rule R1-17B
19 that the Commission initiate a Technical Conference
20 regarding the projected transmission and
21 distribution projects to be included in the PBR
22 Application.

23 On June 15th, 2022 the Commission issued
24 its Order Scheduling Technical Conference and

NORTH CAROLINA UTILITIES COMMISSION

1 Setting Procedures for Technical Conference,
2 scheduling the Technical Conference to be held on
3 this date, July 25th, 2022 beginning at two o'clock.
4 The purpose of this Technical Conference which is
5 required by Statute is to allow DEP to present
6 information regarding its projected transmission and
7 distribution expenditures.

8 The Commission's June 15th Order permits
9 interested parties with the opportunity to intervene
10 in the docket and to provide comment on DEP's
11 filing. The Order also permits parties an
12 opportunity to make a presentation today subject to
13 an advanced notice requirement.

14 Upon the filing of timely motions, the
15 following parties have petitioned to and have been
16 allowed to intervene in this proceeding. The
17 Carolina Industrial Group for Fair Utility Rates II;
18 Carolina Utilities Customer Association; North
19 Carolina Justice Center; North Carolina Housing
20 Coalition; and the Southern Alliance for Clean
21 Energy, to which I'll collectively refer to as NCJC;
22 the North Carolina Sustainable Energy Association;
23 Vote Solar; the National -- Natural Resources
24 Defense Council or the NRDC; and the North Carolina

NORTH CAROLINA UTILITIES COMMISSION

1 Electric Membership Corporation filed a Petition to
2 Intervene which was denied, but NCEMC has been
3 allowed limited participation rights and will be
4 allowed to participate in the Technical Conference
5 today, if so willing.

6 The North Carolina Attorney General's
7 Office has provided notice of its intervention in
8 this proceeding pursuant to North Carolina General
9 Statute § 62-20. And the Public Staff which
10 represents the Using and Consuming Public in matters
11 before the Commission has provided notice of its
12 intent to participate in the Technical Conference
13 today.

14 On July 15th, 2022, DEP filed its
15 projected transmission and distribution
16 expenditures. In accordance with the Commission's
17 Order issued on June 15th, parties may file written
18 comments on DEP's filing through today, July 25th.
19 That brings us to today.

20 Today, we're going to hear first from DEP.
21 There will be no cross examination of the DEP
22 witnesses per the terms of the Statute, but
23 Commissioners will be permitted to ask questions of
24 DEP's witnesses. There will be no questions taken

1 on Commission's questions.

2 Parties who have indicated an intent to
3 present will be allowed no more than 10 minutes each
4 to make such presentation. The Commission will hear
5 from those parties in the following order: The
6 Public Staff, the Attorney General's Office, NCEMC,
7 CIGFUR, NCJC, NCSEA, and Vote Solar.

8 This Technical conference is being
9 transcribed and the transcription -- and the
10 transcript will be filed in the docket as soon as
11 it's available. Please, as it always the case, do
12 your best today to avoid interference with our court
13 reporter's ability to transcribe the proceeding.

14 Before we begin, I'd like to ask the
15 parties to identify themselves for purposes of the
16 record. We'll start with DEP.

17 MR. JEFFRIES: Thank you, Chair Mitchell,
18 Members of the Commission. I'm Jim Jeffries with
19 the Law Firm of McGuireWoods, and I'm here today
20 along with my co-counsel Ms. Melissa Butler from the
21 Law Firm of Troutman Pepper, and we're here on
22 behalf of Duke Energy Progress, LLC. And we've
23 also -- since we're presenting first, if I may, I'd
24 go ahead and introduce our presenters or --

NORTH CAROLINA UTILITIES COMMISSION

1 CHAIR MITCHELL: Let's hang on one second.
2 Let me get counsel first, and then I'll come back to
3 you for that. All right. Good afternoon,
4 Mr. Jeffries and Ms. Butler.

5 MS. LUHR: Nadia Luhr with the Public
6 Staff on behalf of the Using and Consuming Public.

7 CHAIR MITCHELL: Good afternoon, Ms. Luhr.

8 MS. CRESS: Good afternoon. Christina
9 Cress with the Law Firm of Bailey & Dixon, here on
10 behalf of CIGFUR II.

11 CHAIR MITCHELL: Good afternoon,
12 Ms. Cress.

13 MS. JONES: Taylor Jones on behalf of
14 NCSEA.

15 CHAIR MITCHELL: Good afternoon,
16 Ms. Jones.

17 MR. NEAL: Good afternoon, Chair Mitchell,
18 Commissioners. David Neal on behalf of North
19 Carolina Justice Center, North Carolina Housing
20 Coalition, Southern Alliance for Clean Energy, and
21 Natural -- Natural Resources Defense Council joined
22 together with the Justice Center.

23 CHAIR MITCHELL: Okay. Thank you.

24 MS. FORCE: Good afternoon. My name is

NORTH CAROLINA UTILITIES COMMISSION

1 Margaret Force with the Attorney General's Office
2 representing the Using and Consuming Public.

3 CHAIR MITCHELL: Good afternoon,
4 Ms. Force.

5 MR. LEDFORD: Good afternoon. Peter
6 Ledford, also on behalf of NCSEA.

7 CHAIR MITCHELL: Good afternoon,
8 Mr. Ledford.

9 MR. DROOZ: And David Drooz representing
10 Vote Solar. Jake Duncan is the staff from Vote
11 Solar who is here today. He is not going to be
12 making oral comments and thus, I'll probably step
13 out early as he will just be an observer.

14 CHAIR MITCHELL: All right. Thank you,
15 Mr. Drooz.

16 MR. DODGE: Good afternoon, Chair
17 Mitchell, members of the Commission, I'm Tim Dodge
18 here with North Carolina Electric Membership
19 Corporation. And we do not plan to present any --
20 make any presentations today.

21 CHAIR MITCHELL: Good afternoon,
22 Mr. Dodge. Thank you, counsel.

23 Before we begin, any preliminary matters?

24 (No response)

NORTH CAROLINA UTILITIES COMMISSION

1 We will go ahead and get started. Mr.
2 Jeffries, Ms. Butler, y'all may proceed.

3 MR. JEFFRIES: Thank you, Chair Mitchell.
4 I'd like to begin by introducing the three
5 presenters for Duke Energy Progress today in the
6 order in which they will present. And from the
7 Commission's right to left, we have Mr. Justin Brown
8 who is the Director of Planning and Regulatory
9 Support for Duke Energy. In the center, we have
10 Mr. Brent Guyton who is the Director of Asset
11 Management for Customer Delivery for Duke Energy.
12 And on the Commission's left, we have Mr. Dan Maley
13 who is the Director of Transmission Compliance
14 Coordination for Duke Energy.

15 And at this point, we would turn the
16 presentation over to Mr. Brown.

17 CHAIR MITCHELL: All right. Good
18 afternoon, gentlemen. You may proceed.

19 MR. BROWN: Good afternoon. Thank you for
20 -- to all the attendees who have joined us today for
21 this Technical Conference. I know your time is
22 valuable. Hopefully, you'll find today's material
23 informative. Again, my name is Justin Brown. I'm
24 Director of Planning and Regulatory Support for Duke

1 Energy.

2 I have seated next to me two experts that
3 will be speaking on distribution and transmission
4 investments that will be included in the multiyear
5 rate plan projects. First speaker is Brent Guyton,
6 Director Asset -- excuse me -- Director of
7 Distribution Asset Management. Brent will be
8 followed by Dan Maley, Director of Transmission
9 Compliance and Coordination.

10 So we'll spend the next few minutes going
11 through and hearing from the experts on discreet and
12 identifiable distribution and transmission-related
13 projects that we expect to file in our multiyear
14 rate plan.

15 Over the course really of this Technical
16 Conference, we're going to provide an overview of
17 the trends that are impacting our industry and drive
18 our system planning. We're also going to share an
19 overview of the distribution and transmission
20 projects as I mentioned earlier that were included
21 in our pre-conference technical documentation filed
22 back on July 15th. These investments are necessary
23 for the Company to both maintain and advance the
24 grid to support the clean energy transition in North

1 Carolina.

2 Additionally our speakers are going to
3 provide specific examples of projects and programs
4 to be included in the multiyear rate period. It's
5 also important to note the presentation today we're
6 going to go over at a high level. It's not going to
7 go through every piece of documentation that we
8 previously filed but hope to give a good overview of
9 those.

10 Just as a reminder, the documents that we
11 did share in advance on July 15th provide really a
12 detailed description of each planned improvement
13 program or project. The purpose and the description
14 of those projects of the work to be completed, a
15 summary of benefits, the estimated installation cost
16 for both T&D work.

17 Additionally, we provide a complete list
18 of the planned projects that included the projected
19 in-service dates, the estimated total cost for each
20 individual project along with House Bill 951 policy
21 considerations that are addressed.

22

23 And lastly, cost/benefit analyses. We did
24 list cost and benefits of each program and project,

1 and many include a financially-based cost/benefit
2 analysis.

3 We want to address upfront the federal
4 grants, being the Infrastructure Investment Jobs
5 Act, IIJA. We are actively engaged in ongoing
6 implementation of the federal Infrastructure
7 Investment Jobs Act at the state and federal level.
8 We are participating in requests for information and
9 also having discussions both at the federal level
10 with the Department of Energy, Department of
11 Transportation, as well as the EPA.

12 For instance, we did file a RFI in early
13 June, June 2nd, along with five other RFI responses
14 that have been submitted, I believe in the open
15 docket, for the Commission already, the IIJA docket.
16 While federal agencies are making progress, they
17 still are in the early phases of the implementation
18 of the federal grants with many activities under
19 development.

20 While programs are under development, the
21 Company is defining and working through a
22 prioritization process that includes building a
23 framework and operating model with a partnership
24 with an outside firm that we plan to benchmark

1 against our industry peers.

2 The process will include proactive grant
3 planning. We expect the grant windows to be fairly
4 short, 60 to 90 days when those become available, so
5 we kind of need to have our act together in that
6 approach. Also includes grant writing, submittal,
7 and our execution plans associated with that.

8 The team is going to carefully review those grants
9 and may apply at both the federal and state level to
10 participate. Our goal is essentially to maximize
11 the impact of those grants for customers in North
12 Carolina.

13 We look forward to the funding
14 opportunities that are expected to become available
15 in the fourth quarter of this year. But to be
16 clear, we are pursuing the funding opportunities for
17 the benefit of customers and we will ensure that
18 they receive the benefits associated with those
19 grants.

20 The projects included in our multiyear
21 rate plan and in the materials submitted on July
22 15th, however, don't include an assumption for any
23 grants received. The projects benefit customers
24 regardless of whether the grant opportunities are

1 made available to the Company. So none of the
2 cost/benefit analysis or the listing of cost and
3 benefits assume any grant awards.

4 So overall, I believe we would all agree
5 that our grid is in a complex transition. The
6 original design of our grid was somewhat simple and
7 had a few key design assumptions that were -- that
8 were in place. One, that overall generation was
9 firm and dispatchable. The generation generally
10 followed load and always kept the power in balance.
11 Load at the distribution level of the system was
12 treated more as a passive load as opposed that was
13 attached to the transmission system. Power flowed
14 generally in one direction from central generation
15 to the customer, and the grid was designed for
16 reliability.

17 Overall, the mission of the electric
18 utility has significantly changed over the decades.
19 Our mission used to be to keep the lights on, keep
20 the lights on, and keep the lights on. Now today,
21 we are faced with other considerations. One, we
22 have to be cyber secure. We have to be physically
23 secure. The grid has to be flexible in enabling new
24 technologies that are coming on the grid. We have

1 to be accessible, economical, clean, and
2 sustainable, and upmost we have to be resilient.

3 Today, those original design assumptions
4 that I mentioned earlier are being challenged. We
5 introduced back in 2019 mega trends or trends that
6 we are looking at that are affecting our grid
7 investments. Those are still present today. One
8 being grid improvement, technologies. Overall,
9 those technologies are continuing to advance at a
10 very high rate. Spending in smart grid IT and
11 analytics overall is expected to grow to \$6 billion
12 by 2028. Technological advancements with renewables
13 and DER is growing rapidly, especially here in North
14 Carolina.

15 As I mentioned earlier, threats to grid
16 infrastructure unfortunately is troublesome. The US
17 and the US ransomware attacks are up by 148 percent
18 over 2020. The impact of weather events is
19 increasing in frequency. North Carolina has been
20 impacted six times by billion dollar storms in some
21 way in 2021, and nine of those billion dollar storms
22 in 2020, the most in North Carolina history.

23 Concentrated population growth continues
24 to occur in North Carolina. North Carolina has two

1 cities, Charlotte and Raleigh, that are among the
2 top 25 cities growing in the United States.

3 Customer expectations are continuing to
4 evolve with reliability and affordability being key
5 to their fact topics to us.

6 And finally, environmental commitments
7 both at the federal, state, and local levels.
8 Fortune 500 companies are seeking places to invest
9 that are -- have carbon reduction and sustainability
10 in mind. Sixty percent of the Fortune 500 companies
11 have carbon goals, much of those located in North
12 Carolina.

13 And key among that is House Bill 951.
14 Those in the House Bill 951 establish aggressive
15 carbon goals, 70 percent by 2030, and net zero by
16 2050. The grid improvements proposed are necessary
17 to not only maintain our grid, but also support the
18 clean energy transition and the overall resiliency
19 of our grid in North Carolina.

20 When we start thinking about the future of
21 the grid, we have to start thinking about it as an
22 enabler. The grid has to be thought of as an
23 enabler for new technologies that safely integrates
24 new grid edge technologies growing the ER technology

1 such as solar, wind, storage, and electric vehicles.
2 To do this, the legacy grid must be upgraded and
3 adapted to accommodate two-way power flow, load
4 shifting, and greater situational awareness.

5 Traditional forms of grid planning are no
6 longer adequate. The Company has implemented
7 Integrated Systems Operation Planning or ISOP. And
8 those plans leverage more and more data such as the
9 propensity to adopt solar and the purchase of
10 electric vehicles and all that has to be implemented
11 into our planning processes.

12 Overall, programs will use new processes
13 to implement tailored solutions that essentially is
14 going to build a digital super structure grid that
15 delivers on the energy goals for North Carolina and
16 the requirements for our state.

17 So when we start thinking about the
18 overall strategy and the future grid, a couple of
19 things bubble up to mind. Three primary adjustments
20 really come to mind. One is overall grid
21 resiliency. We must have a grid that has the
22 ability to withstand and recover from frequent
23 extreme weather events and external hazards. The
24 grid must have -- must be more resilient if we're

1 going to have more and more DER attached to the
2 distribution system overall. Expansions of
3 renewables and DER, the grid must be able to meet
4 that customer demand and be able to accommodate it.
5 If North Carolina has a bold carbon goal, both the
6 distribution and transmission system must be ready
7 for that challenge.

8 And overall, finally, equitable access to
9 benefits. We must achieve a balanced outcome for
10 all customers across the state to be able to
11 accommodate and be able to leverage the new energy
12 technologies and solutions that are coming. And all
13 this has to be done with an eye towards the most
14 efficient manner of implementation and
15 affordability.

16 So next I'm going to turn it over to Brent
17 Guyton who will dive into the distribution programs.
18 Brent?

19 MR. GUYTON: All right. Thank you,
20 Justin. And good afternoon everyone. My name is
21 Brent Guyton. I'm the asset -- or Director of Asset
22 Management for Distribution here in the Carolinas.
23 During my portion of the presentation today, I'm
24 going to cover six areas. One, benefits to

1 customers. Also talk about the four critical grid
2 capabilities needed to achieve the objectives that
3 Justin just touched on.

4 I'll also overview the work streams and
5 programs that are in our distribution projects.
6 Also the planning approach that we've leveraged to
7 maximize benefits to our customers. I'll also
8 overview a specific MYRP project in our coastal zone
9 in the greater Wilmington area. And then lastly,
10 I'll highlight the 10 program summaries that make up
11 our MYRP project support streams within those.

12 Before I do that, I want to talk briefly
13 about -- about how we will be delivering the
14 benefits to the customers and establishing and/or
15 strengthening those critical grid capabilities that
16 I'll describe shortly. I'll explain this more as we
17 go along through my part of the presentation, but I
18 want to introduce it here as we get started.

19 So our projects are planned for a set of
20 geographically clustered substations. Each
21 substation based on its specific needs to achieve
22 those grid capabilities will receive selected
23 distribution improvement programs. It is not a
24 one-size-fits-all. You will see that as I talk

1 about the specific project for the coastal area.
2 And lastly, the work is executed geographically for
3 those clustered substations to maximize, one,
4 resource efficiency; two, minimize the disruption to
5 our customers while we're performing the work, and
6 also deliver the customer benefits across a broad
7 customer area or footprint as we complete that work.
8 All of that infrastructure is uplifted as to the new
9 grid capabilities.

10 So the benefits from doing this work.
11 First off, reliability. Fewer and shorter outages.
12 I'll describe some of the programs that will support
13 this from self-optimizing grid to targeted
14 underground as well as others.

15 Resiliency, as Justin talked about,
16 physical and cyber attacks are certainly a threat,
17 but also severe weather impacts. We have specific
18 programs and work to deal with those as well.

19 Access to renewables and distributed
20 energy resources. Capacity and voltage regulation,
21 two of the work streams that we have in our
22 distribution projects, specifically address the
23 ability for two-way power flow to support DER as
24 well as the voltage regulation and management needed

1 with fluctuations in voltage from intermittency in
2 rooftop solar.

3 The MYRP projects and the grid
4 capabilities they bring are foundational for future
5 work and support future technologies. Justin talked
6 about the advancements in grid technologies being
7 one of the mega trends. This work is foundational
8 that we can build on going forward.

9 With enhanced automation and control and
10 also situational awareness, we can operate the grid
11 more efficiently. That's in our control centers.
12 The situational awareness that the operators in
13 those grid -- in the control rooms have allowed them
14 to make better real-time decisions as well as for
15 the automated systems in those control rooms to
16 execute things more effectively and efficiently.

17 Also with the automation and
18 communication, there are huge amounts of new data
19 that we're generating daily that we can leverage to
20 build additional customer programs and offerings to
21 allow them to have more choice around affordability
22 and control of their energy use.

23 And equitable access to benefits. I
24 talked about that a moment ago. As we complete our

1 MYRP projects there across a broad footprint
2 geographic area and uplift those assets and provide
3 the benefits to all the customers in those areas.

4 The strategy that we're implementing as we
5 go through this is foundation and will support
6 customers in the future. The programs and work that
7 we're doing within MYRP projects truly do make the
8 grid more flexible and adaptable, again, to support
9 two-way power flow and distributed energy resources
10 as an example.

11 I talked a moment ago about the automation
12 and control technologies in generating huge amounts
13 of data. Not only is that great for our operators
14 in situational awareness, that's also leveraged by
15 our planning engineers for future planning cycles.
16 Leveraging the ISOP tool sets and the subsets of
17 tools underneath integrated system resource
18 planning -- operations planning. Sorry. And as the
19 grid technologies continue to advance, they'll be
20 integrated in new solutions that will be able to
21 address changing customer needs as well.

22 So I mentioned the critical grid
23 capabilities, and you see the four listed here:
24 Reliability, capacity, automation, and

1 communication, as well as voltage regulation. And
2 let me touch on reliability. There's a historical
3 view and understanding of what reliability means and
4 the impact of outages. That changes in the world as
5 we go forward with distributed energy resources, so
6 let me describe that a little bit.

7 So in the past, the distribution grid, as
8 Justin described, was built to serve customer load.
9 And when there was an outage, customers, residential
10 as well as commercial/industrial, certainly
11 residential if they had a home-based business, and
12 then commercial/industrial, it was an impact to
13 commerce or loss of revenue in that particular
14 instance. And also if someone now in today's world
15 is a hybrid employee or a completely virtual
16 employee working from home, that outage is now
17 impacting their ability to do their job. That's not
18 been the history that we've had.

19 And also along with that homeschooling.
20 That has become more the norm, not just from a COVID
21 standpoint, but continuing to grow. That impacts
22 education for our children in the future when we
23 have an outage. It interrupts their learning
24 process.

1 So now fast forward to the future when we
2 have distributed energy resources that are connected
3 to the distribution grid. Now it is no longer just
4 that traditional impact that I just described.
5 We're impacting the ability of generation to connect
6 and supply power to the grid when we have an outage.

7 You layer into that electric vehicle
8 charging. There's now an impact of an outage,
9 whether it be fleet electrification at a business or
10 charging a personal vehicle at home, that that
11 outage now has an impact on transportation. That
12 has not been the case in the past from a reliability
13 perspective. So very different lens in which we
14 look at reliability going forward.

15 Capacity next. It is critical for two-way
16 power flow to build appropriate hosting capacity
17 into the grid, and there's a traditional view of
18 capacity to just serve traditional loads, but now
19 we've got to layer in both an electrical vehicle
20 charging as well as distributed energy resources.
21 And we do that with our MoreCast tools under ISOP to
22 take in and look at that information, and I'll
23 describe that more in a little bit.

24 Automation and communication. The

1 self-optimizing grid program is really a cornerstone
2 program that defines resiliency. We're able to have
3 a fault condition on the distribution grid. The
4 system in less than a minute detects where that
5 problem is and automatically reroutes power around
6 that. The ability to take a punch and recover
7 quickly at least in my mind is the definition of
8 resiliency and that program does that.

9 And last, voltage regulation. We have
10 always had voltage regulation in the distribution
11 grid to follow traditional load moving up and down
12 throughout the day or during the hours of the day.
13 But as we introduce more and more distributed energy
14 resources and you have cloud cover passing over and
15 a generating site can go from maximum generation to
16 minimum generation in seconds or partial seconds,
17 parts of a second, and do that multiple times during
18 the day, we've got to be able to manage that type of
19 fluctuation and voltage on the distribution grid.
20 That requires new capabilities in voltage regulation
21 management.

22 So that's a lot. Four broad categories of
23 grid capabilities in my description. What I'd like
24 to share is really the kind of analogy of how I see

1 all this coming together. So I want you to think
2 about the vehicle that maybe you learned to drive on
3 or you rode in with your grandparents as you were
4 growing up, and think about the technology that was
5 in that vehicle versus the one that you probably
6 used to commute to this meeting today or maybe
7 sitting at home in your garage now.

8 When I think about reliability or
9 longevity, we used to talk about tune-ups for old
10 cars. You don't hear that term anymore. The cycles
11 of maintenance are much more extended, last longer
12 without having to do any maintenance on those
13 vehicles.

14 Efficiency, likely the vehicles of today,
15 at least for gasoline or diesel engine, they're
16 smaller than the historical vehicles and yet much
17 more powerful and much more efficient based on where
18 they are today.

19 When I think about automation, the first
20 example of automation I can think of in vehicles, it
21 was an automatic transmission versus a manual or a
22 standard shift transmission. We now have things
23 such as climate-control automation, Bluetooth
24 connections to your phone; self-parking vehicles is

1 now part of the automation we see in vehicles today.

2 Control or advances in control, same
3 thing. I think of cruise control as one of the
4 earliest examples I can think of for control in a
5 vehicle.

6 We now have antilock brakes as well as
7 radar on a vehicle where if you set your cruise
8 control and you begin to encroach on the vehicle in
9 front of you, will automatically slow your vehicle
10 down and adjust your speed to maintain a safe
11 following distance. As that vehicle moves out of
12 the way or you change lanes, it will automatically
13 move you back up to your speed while maintaining
14 that distance.

15 And lastly, situational awareness. In the
16 older vehicles you may have had a rearview mirror or
17 side-view mirrors, and now they're surrounded with
18 cameras, again, radar on the front of vehicle to
19 look at closing distance on other vehicles.

20 Think about what you have inside the
21 vehicle with the dash. A simple gauge cluster
22 potentially with a speedometer in the past, and now
23 there's a touchscreen driver information center with
24 multiple screens that you can advance to to make any

1 changes in the vehicles.

2 That's the type of transition that I see
3 in the advancements of technology that's necessary
4 on the distribution grid, and we're on that pathway
5 now. But that gives a broader view, at least in my
6 mind, of how that moves and one that hopefully most
7 of us can relate to. So we're going to talk about
8 the programs themselves that make up our projects.

9 You'll see on the left-hand side of this
10 graph the projected spend over the three rate years,
11 October '23 through the end of September of '26,
12 total of \$1.8 billion projected for the work in the
13 distribution projects. There's three categories you
14 see with substation and line making up the majority
15 of those, but also hazard tree removal as well as
16 retail and system capacity.

17 You'll see those listed again in the
18 center of the table there. And then also there's
19 details further over to the right.

20 One thing I want to point out and speak to
21 is that within substation and line, you see
22 capacity. It's the very first detail that you see
23 listed there at the top. You'll also see hazard
24 tree removal one up from the bottom in the

1 substation and line category.

2 But you'll also see retail and system
3 capacity listed separately and also hazard tree
4 removal. In both cases that's the same work. It's
5 where it's happening geographically that's the
6 difference for those. The capacity work is not only
7 serving traditional loads, but also additional
8 capacity for electric vehicles and distributed
9 energy resources. Within substation and line, it is
10 geographically located with another critical mass of
11 work that could all be executed together as a large
12 project. Whereas the standalone capacity is
13 identified thermal overloads for the three-year rate
14 periods that we need to be addressed, but they are
15 not physically adjacent to other critical work that
16 we can execute as a larger project.

17 The same thing for hazard tree removal.
18 It's the same work both in the substation and line
19 areas as well as the standalone. As part of our
20 integrated resource -- sorry -- integrated
21 vegetation management plans, we have maintenance of
22 our right of ways, so the prescribed right of ways
23 around our distribution lines that we maintain and
24 remove vegetation within the right-of-way, hazard

1 tree removal is focused on threats from outside the
2 right-of-way. Dead, diseased, dying, or otherwise
3 structurally unsound trees that can fall into the
4 right of way and damage and contact our facilities.

5 So again, both of those are needed. We've
6 identified trees that our outside and away from the
7 other projects as well as some that are
8 geographically located but we can execute at one
9 point.

10 The 10 programs that are part of the
11 substation and line, there are short descriptions
12 here on the page, I think, that are very
13 descriptive.

14 Again, capacity is about line capacity
15 both traditional DER as well as EV.

16 Self-optimizing grid or the self-thinking
17 grid, you may have heard that term, is about
18 detecting faults and automatically rerouting power
19 to restore as many customers as possible.

20 Voltage regulation. I describe that as
21 one of the critical grid capabilities and now -- and
22 we also are describing a program that directly adds
23 that capability in.

24 Hardening and resiliency. Justin touched

1 on that as one of the key areas for the grid to
2 strengthen and avoid threats.

3 Specifically, there are three areas I'll
4 talk about as we go into the program summaries and
5 these are focused on more physical threats, both
6 severe weather as well as other impacts to the grid.

7 Equipment -- I'm sorry. Distribution
8 automation. Adding automated restoration
9 capabilities in certain portions of our lines. Also
10 equipment retrofit. This is focused on three
11 different asset classes; transformers, arrestor
12 stations, and riser poles. And riser poles are
13 where our facilities transition from overhead to
14 underground. That last pole where the conductors
15 transition to underground is referred to as a riser
16 pole. There's some equipment modifications that we
17 can make on those to make those more reliable.

18 Long duration interruption. This is
19 looking at areas of our system where the facilities
20 are hard to access. They typically are more remote
21 customers geographically isolated where we may serve
22 entire communities or groups of customers and we
23 have higher than normal duration outages when they
24 do have an event. And I'll talk more about that as

1 well.

2 Targeted undergrounding is a data-driven
3 approach to look more at the laterals of our system
4 and where we have unusually high frequency of
5 outages and potentially placing those underground,
6 and also relocating from typically rear lot to front
7 lot as well.

8 I talked about hazard tree removal and
9 I'll describe that more as we get to the program
10 summary.

11 And then lastly, infrastructure integrity.
12 This is about looking at the foundation of the grid
13 on which we'll build all the other work that's there
14 and make sure everything is intact while we're in
15 that area executing those larger projects. Make
16 sure everything is where it needs to be to support
17 the ongoing needs of our customers from that.

18 All right. I want to talk about how we
19 actually plan and build out and assemble the MYRP
20 projects.

21 Overarching this, and I'll go ahead and
22 say this here, the integrated systems and operation
23 planning tool sets are a key part of this,
24 especially for our distribution planning engineers

1 with the advance distribution planning tool sets as
2 well as the MoreCast load data that's leveraged to
3 look at capacity needs going forward.

4 I'm going to start on the graphic and
5 really from kind of the lower left, that seven
6 o'clock position and work my around clockwise as we
7 get through this.

8 We do at the -- so planning engineers,
9 they are assigned a geographic area. There's a set
10 of substations and circuits that they have personal
11 responsibility for to do all the analysis and load
12 flows and calculations that are necessary here.
13 They do that at a circuit level, but they're also
14 looking broader across the area at the roll-up to
15 substations in their areas also.

16 The first thing to do is leverage the
17 MoreCast dataset. That's a 10-year hourly view
18 within our ISOP tool sets providing load information
19 for the planners to analyze. It not only looks at
20 traditional loads, but also electric vehicle impacts
21 as well as distributed energy resource impacts as
22 well. And all that is included in that capacity
23 analysis.

24 They're also looking at the other critical

1 grid capabilities I mentioned; reliability, voltage
2 regulation, as well as automation and communication.
3 Once they've identified that current state and where
4 there are potential gaps in the capabilities for
5 those -- those individual circuits, those are then
6 looked at across those -- all 10 of those programs
7 to layer in an approach to look at what the benefits
8 are that could be delivered to customers and how we
9 could actually raise the capabilities for those --
10 for those circuits.

11 That then is really the balanced circuit
12 approach; the outcome of that looking at what's
13 needed for individual circuits. And again, it's not
14 a one-size-fits-all. It's based on the analysis
15 they've done of what the needs are for those
16 individual circuits.

17 This is where you see in the middle of the
18 graphic, you see project development and also asset
19 management listed, the duties I've spoken to so far
20 as within asset management. But this next step is
21 where project development gets involved, so they
22 collect and intake all that information from the
23 planning engineers across the system and start to do
24 a system-level analysis. What is all the work that

1 is necessary across the system within this
2 particular MYRP period?

3 That then is iterated against things such
4 as any potential labor constraints, any material
5 issues that we may know about, as well as annual
6 budgets. That is an iterative process and then
7 developing -- these are the annual plans to be
8 developed into MYRP projects.

9 That then begins the process of sequencing
10 that work at high level schedules for the individual
11 substations, and then those geographically clustered
12 stations that is all aggregated together to form the
13 MYRP projects for that.

14 One thing I want to mention is I've talked
15 about MoreCast being a 10-year hourly forecast to
16 look out over that 10-year horizon. That 10-year
17 horizon is necessary to truly give transmission and
18 generation a view of what impacts distribution will
19 have on the overall system and how they incorporate
20 that into the Integrated Resource Plan.

21 The planning engineers while they have
22 that 10-year view, they're not looking to scope
23 projects and solve problems that are in years six
24 through 10. They are focused on years three through

1 five. What are the near-term thermal issues,
2 automation capabilities, voltage regulation needs,
3 as well as reliability in that three-to-five year
4 window? That's the work that needs to be executed
5 now and plan now for the next three years. We will
6 then come back and analyze again in the future and
7 continue that iteration and pick up those
8 out-of-year projects as appropriate in the future.
9 So again, a proper planning horizon, not over
10 building, but look at near-term needs for the grid.

11 So we'll take a look at a project. This
12 is a fairly busy slide, but before I move over here
13 to the table, I want to talk about what's in the box
14 on the left. And I talked about this earlier, so I
15 want to circle back to some of my earlier comments.

16 The project-based approach that we
17 leverage. Again, we analyze at the circuit level,
18 roll that up into plans for Duke geographically set
19 of substation -- or geographically located
20 substations. We select only the improvement
21 programs that are needed. It's not a
22 one-size-fits-all. What are the things needed for
23 those circuits? And again, only in that
24 three-to-five year window.

1 And lastly, the improvement programs are
2 selected. Those are then rolled into MYRP projects
3 for -- to be executed and also at that
4 geographically clustered level.

5 And the reasons for that is to maximize
6 resource efficiency. We move and mobilize into an
7 area, do all the work that's necessary, and then
8 demobilize and move to the next area. That
9 minimizes customer disruptions. Yes, we're still
10 there working, but we're in there and out of there
11 as efficiently as we can. And when we leave, the
12 benefits to the customers are all there. Everything
13 that we were going to do on behalf of the customer
14 is complete as we roll out of that area and move to
15 the next area.

16 I'll share another analogy I think that
17 helps describe this a little better. Think about a
18 house remodel. And I'm not talking about one
19 individual room. I'm talking about a whole house
20 type of remodel. The first thing you'll do is think
21 about what the needs are that you have for your
22 house. There may be things that are end-of-life
23 assets. You may want to improve the efficiency of
24 your home. Maybe it's an older home. Replace

1 windows, doors, insulation, new HVAC system. Maybe
2 the plumbing is an older vintage of metal pipes as
3 opposed to modern plastic pipes.

4 There may be things that you need from a
5 home automation standpoint, upgrades to appliances,
6 et cetera. Possibly a new roof. You may have to
7 start taking care of aging parents. You may have to
8 create an aging-in-place benefits and areas in your
9 home to be able to accommodate them.

10 So once you've identified all that,
11 there's a couple of ways you could execute that
12 house remodel. One, you can do a lot of small
13 individual projects. It likely takes a long time.
14 Future projects as you do the smaller ones may end
15 up impacting a project you just finished and there
16 may -- it may cause you to undo something you just
17 did to complete the next little project. It
18 certainly seems less efficient, and the disruption
19 to you and your family as you're going through this
20 remodel seems to go on forever. There's no end in
21 sight what's going there.

22 And even as you complete each of the
23 individual projects, it's really hard to appreciate
24 the benefit that you brought by completing that one

1 project, because there's so much other things that
2 still aren't where you need them to be providing
3 those benefits.

4 Contrast that with all the same needs that
5 you have for your home remodel, but you aggregate
6 all that into an overall project for the entire
7 remodel of all -- of your entire home. You still
8 identify all those things you need to change or
9 upgrade and things you need, but you likely hire a
10 general contractor and other professionals to come
11 in and look this over. Aggregate all that into one
12 project, sequence the trades that come in, and take
13 apart to do the individual parts and work streams of
14 that. That minimizes any rework. It is still
15 disruptive and inconvenient for your family, but it
16 has an end. And when that general contractor walks
17 out the door for the last time, you and your family
18 enjoy all the benefits and things you were trying to
19 accomplish with the house remodel. It's one and
20 done as opposed to seemingly go on forever.

21 And just like the remodel that I may do
22 versus Justin, each one is different, and you'll see
23 that for our substations projects where they're
24 individualized for those substations and circuits

1 within the MYRP projects.

2 We'll take a look now at the sample
3 project there. This is actually in our coastal zone
4 and this is area 282 which is the greater Wilmington
5 area. You'll see that it's made up of 21
6 geographically clustered substations, and their
7 names are listed down the left-hand side of this
8 table. You'll see the ones at the bottom have the
9 word Wilmington in them. Again, that's the greater
10 Wilmington area including outlying areas as well.

11 Across the top in the blue headers, you'll
12 recognize those 10 categories are column headers as
13 the programs that I described briefly earlier, and
14 we'll go into more detail with the program
15 summaries.

16 I put a box around one of the substations
17 there in the middle, Murraysville. And you'll
18 notice that out of the 10 programs there are only
19 six selected for that substation, and the reason for
20 that is there are not any capacity needs or
21 self-optimizing grid needs in the next three to five
22 years for Murraysville substation. That work is
23 either already been done previously or it doesn't
24 show up in our cycle planning until after year five.

1 So it's in those out years that we'll catch in a
2 future cycle from that perspective.

3 You'll see other variability across the
4 other substations listed within this MYRP project.
5 And again, the same application applies. The
6 analysis was done. The work is not needed at this
7 time. And where you do see the checkmark, there is
8 a roll-up of that type of activity on that
9 substation.

10 I'll reiterate again here what I said
11 earlier, that really we're looking for these
12 projects in that three-to-five year timeframe. What
13 are the critical grid capabilities needed then, not
14 out to as far as we can see with the MoreCast tool
15 in the 10 years. This is focused in on the front
16 half of that planning horizon.

17 One last comment I'll make while I'm on
18 this slide. The maturity of the estimates that we
19 have in our file materials for this Technical
20 Conference these estimates are all as of early June.
21 We certainly are facing other economic
22 uncertainties. And as we refine our estimates
23 through our process, we'll make sure through the
24 appropriate vehicle to make sure the Commission and

1 all stakeholders are informed of what those changes
2 are if some of these do change going forward.

3 All right. We'll now move into the
4 program summaries. And as I talk about each one of
5 these programs, there's two slides for each program.
6 The first one will be a program overview like you
7 see on the screen here for capacity. There will be
8 a second slide for each one that focuses on the
9 benefits of doing that particular work or work
10 stream.

11 For -- also you'll see -- well, let me
12 talk about this first, then I'll touch it before I
13 leave the slide. Capacity upgrades are not new.
14 But as I described earlier, the new layers and areas
15 of capacity that we've got to look at are electric
16 vehicle adoption as well as distributed energy
17 resources and the two-way power flow necessary to
18 accommodate those. That is all part of, as I
19 mentioned a couple of times earlier, part of the
20 MoreCast data that's leveraged for the capacity
21 analysis for each of the circuits that we look at.

22 There's also the automated distribution
23 planning tool set which is part of ISOP. That
24 includes automated solutioning which allows us to

1 analyze, or a planner to analyze, not only at the
2 circuit level for the individual thermal overloads
3 that are identified, but also in that area adjacent
4 circuits and substations leveraging that MoreCast
5 peak data on how to best alleviate that thermal
6 overload. And that may include balancing load
7 transfers to other -- permanent load transfers to
8 other circuits, conductor and device upgrades which
9 are more traditional capacity implementation, as
10 well as nontraditional solutions also.

11 You'll see -- in the program description
12 box you'll see two different headers; retail
13 capacity and system capacity. And I want to take a
14 moment to explain what the difference is for -- or
15 difference between those are.

16 They're both necessary for the same
17 reasons, which is support traditional loads as well
18 as DER and electric vehicles. The retail capacity
19 work refers to upgrades or work done on our
20 transmission to distribution substations. We call
21 those retail stations, because they are the
22 substations that serve distribution's retail
23 customers as opposed to transmission's wholesale
24 customers that they serve from other types of

1 substations.

2 The work that would be included for retail
3 substations would include transformer upgrades or
4 new transformers within the substation. It may
5 include breaker additions if a new distribution
6 circuit is needed outside of the substation. And it
7 could even be a new substation in an area that's
8 growing quickly and serving that load center from
9 other stations that exist in that area is not
10 practical from that perspective. So think of retail
11 capacity work as work inside the substation fence.

12 System capacity is really the opposite of
13 that. It is work outside the substation fence on
14 the distribution lines, again, serving the same
15 types of capacity needs. And this would include
16 upgrades to wires and/or equipment as well as new
17 circuits to serve growing load in certain areas. So
18 retail capacity is inside the fence. System
19 capacity is outside the substation fence.

20 In each one of the program overview
21 slides, you'll see estimated construction on the
22 right. Estimated construction timelines, estimated
23 in-service dates, as well as projected costs. And
24 in the bottom half of that box, you'll see critical

1 grid capabilities and -- sorry -- critical grid
2 capabilities enabled, and that refers back to the
3 four that I talked about earlier: Capacity,
4 reliability, voltage regulation, and automation and
5 communication. And then lastly in the bottom, House
6 Bill 951 policy considerations that are also
7 addressed.

8 I won't spend much time on those. I'll
9 focus on what the program is as well as -- as well
10 as the benefits for each of those.

11 So let's talk about the benefits for
12 capacity. Reliability and resiliency and expanding
13 the solar renewables. Without doing proper capacity
14 upgrades, we risk failures of overloaded conductors
15 and equipment at peak times. Therefore, building in
16 the necessary capacity in advance at the right time
17 reduces potential outages from those conditions.

18 Capacity improvements also help from a
19 resiliency standpoint. While it certainly can be
20 leveraged for the traditional means, it also
21 provides alternate paths for switching and other
22 redundancy when we have impacts to the grid.

23 And I've mentioned a couple of times
24 already capacity enables two-way power flow, which

1 thus supports additional renewable energy resources
2 as we transform the grid to more carbon free
3 sources.

4 So self-optimizing grid. I mentioned
5 earlier this is a cornerstone program for
6 distribution and addresses actually multiple
7 critical grid capabilities. If you go ahead and
8 look to the lower right, you'll see that three of
9 the four are addressed by this singular program, and
10 that's the reason I call it a cornerstone program
11 for distribution. It addresses not only
12 reliability, but also capacity and also automation
13 and communication as well.

14 As we're scoping and identifying
15 self-optimizing grid needs, this is an area also
16 that specifically the planning engineers leveraged
17 the ISOP tool sets such as advanced distribution
18 planning, and there's even a sought automation
19 portion of those ADP tool sets that also provides
20 suggested automated placement of those switching
21 devices along the circuits that they're studying.
22 The planners still review that for -- to see whether
23 that makes sense or not, but they do -- are
24 presented with automated solutions based on the

1 criteria for self-optimizing grid.

2 There's three major components to
3 self-optimizing grid. You see those listed in the
4 program description. First off, capacity. So you
5 may be thinking okay, we just talked about capacity
6 and you're talking about capacity again, so let me
7 explain the difference between the two.

8 The previous capacity that I spoke of is
9 going to serve what I'm going to call native load
10 for a particular circuit. So in that -- in the
11 normal situation, this is all the load that that
12 circuit has to serve traditional EVs as well as
13 DERs.

14 Self-optimizing grid. The purpose of that
15 is to have two circuits or more that provide backup
16 capability to adjacent circuits. So it's not only
17 do I -- does circuit A have to serve all of its
18 traditional load. If circuit B has a problem,
19 circuit A needs to pick up some of those customers
20 and pick up some of that load. So that's additional
21 capacity for what I'll call emergent conditions or
22 impacts to the grid, not just that native load
23 that's on the circuits.

24 The same analysis occurs and the planning

1 engineers are actually looking at both of those at
2 the same time and one that's not doing multiple
3 work. It's the same work. And it either will solve
4 both problems or they're trying to solve one. But
5 they look at that together for both so that we're
6 doing it one time and one time only.

7 Connectivity. I talked about the two
8 circuits needing to back each other up to be able to
9 form that. They have to be physically connected
10 with a strong tie to transfer load back and forth in
11 outage or fault conditions.

12 And lastly, the automation and
13 communication. This is about applying those
14 intelligent switches out on the grid, also the
15 automation software back in our control centers that
16 provides command and control usually in less than a
17 minute when it detects a fault situation to restore
18 as many customers as possible for that.

19 There is a schematic in the middle of the
20 diagram or middle of the slide at the bottom. I
21 think it's much easier to see in the detailed
22 program summary. Let me describe what that is.
23 That's actually a schematic for an actual
24 self-optimizing grid in our DEP North Carolina

1 territory. This one is actually in -- just adjacent
2 to the Asheville airport, so it's in the western
3 part of DEP's territory.

4 What you'll see is, toward the top of that
5 picture there's two circuits that originate from one
6 substation. The one that goes down and to the left
7 is the Airport Road circuit and serves the Asheville
8 airport and surrounding areas. There's also one
9 that goes down and to the right and that serves the
10 Fletcher area to the east of the airport.

11 What this is indicating, you'll also see
12 several boxes or squares. Some are -- a couple of
13 green, some are red, and some are red crosshatched.
14 Those represent the automated switches that have now
15 been placed on those circuits as part of the
16 self-optimizing grid.

17 Also you'll see what looks like a cloud
18 and a lightening bolt kind of in the upper left
19 toward the center. That's indicating between those
20 two green boxes that we actually have a fault
21 condition on the circuit and in less than a minute
22 the system has determined where that fault is. It's
23 opened those two green switches - green means open
24 for us - and then closed all the other appropriate

1 switches to restore as many customers as possible,
2 all in less than a minute without human
3 intervention.

4 The operators in the control room are
5 aware of what's happening and can take additional
6 steps as necessary, but that's what the
7 self-optimizing grid does.

8 And one last piece of information here.
9 So within -- between those two green switches that
10 you see where the fault is, there's 488 customers
11 that are -- that have a sustained outage until a
12 crew can respond, find the problem, and fix it.
13 Before self-optimizing grid was placed on these two
14 circuits, that same fault event would've resulted in
15 2,691 customers having a sustained outage. So from
16 2,691 customers with a sustained outage to 488.
17 That's what self-optimizing grid can do for us and
18 for our customers.

19 So one other analogy I'll share here is if
20 you think about the grid of the past, and Justin had
21 a slide that talked about this, think about a
22 bicycle wheel. You've got the hub and you got
23 spokes going out to the wheel. That's a very
24 simplified representation of what the historical

1 distribution grid looked like. You can think of the
2 hub as being centralized generation or a substation,
3 and then the circuits go out to serve the
4 traditional loads.

5 Now, think about a spider web. Spider web
6 still has a center. It still has those radial
7 spokes that go out to attach to the doorframe or the
8 tree limb or wherever the spider built it. But
9 there's also dozens if not hundreds of connections
10 between each of those spokes all the way around the
11 grid. That's the type of inter-connectivity that's
12 necessary in the future to be able to support
13 distributed energy resources. Multiple pathways to
14 move power and restore power if needed across the
15 distribution grid.

16 Let's talk about -- I've talked about
17 benefits, but we'll go to the benefits page for
18 self-optimizing grid. Certainly, reliability and
19 resiliency in this case go hand in hand. One, we're
20 preventing sustained outages from a huge number of
21 customers in that example. But also, the system
22 itself is able to take a punch and respond quickly
23 to a fault condition and recover automatically as
24 many customers as possible from a resiliency

1 standpoint.

2 I mentioned again -- or earlier that it
3 supports solar renewables because we are building
4 capacity for emergency backup. That same capacity
5 can be used to move distributor energy resource
6 generation around the distribution grid.

7 And lastly, at the bottom you see the
8 benefit/cost ratio of 5.5 for the self-optimizing
9 grid work.

10 So voltage regulation and management.
11 This is specifically work to address the grid
12 capability that I described earlier of managing
13 those fluctuations. And as I said earlier, voltage
14 regulation is not new, but the impact to DERs, as
15 the penetration becomes higher and higher, is to
16 mitigate the voltage fluctuations that occur from
17 generation moving from max to min as clouds pass
18 over.

19 There's really three that, we say three
20 levels to the program. I'll say three different
21 types of work we do. The first is additional
22 voltage regulators installed on the grid to be able
23 to manage those fluctuations. But also for existing
24 voltage regulators, we installed new controls that

1 are capable of determining two-way power flow.
2 Current controls are built to look at the substation
3 as the stiff source of power and only regulating
4 voltage down stream of that. These new regulators
5 or the new controls have to be able to look in both
6 directions and properly mitigate voltage
7 fluctuations.

8 Capacitors. Capacitors are not new on the
9 distribution grid. That supports or provides
10 reactive power support and voltage regulation
11 reactive power support work hand in hand to properly
12 manage voltage levels on the distribution grid for
13 that. But there will be additional capacitor needs
14 as we move into higher and higher penetrations of
15 DER.

16 The new part of this is actually power
17 electronics. Power electronic devices have the
18 ability to both manage and control voltage as well
19 as provide reactive power support and do that almost
20 instantaneously. That is the new capabilities that
21 are needed in the future.

22 One will have those rapid fluctuations
23 from DERs, but also think about traditional
24 regulators and capacitors were meant to follow load

1 throughout the day, raise voltage and VAR support,
2 and as the load came down in the evenings move back
3 the other direction.

4 With intermittency, those maybe have the
5 potential to chase voltage fluctuations during the
6 day and always be following trying to chase that.

7 The power electronics can damp out those
8 rapid changes and manage those where truly the
9 regulators and capacitors perform the more
10 traditional function of increases as load moves up
11 and down during the day from that perspective.

12 One other way to think about that is think
13 of capacitors and regulators as the course, voltage,
14 and reactive power adjustments and the power
15 electronics give you that not only fine adjustment,
16 but also instantaneous adjustment to deal with those
17 fluctuations.

18 So let's talk about the benefits for
19 voltage regulation. And this is really about
20 maintaining proper voltage levels. We're required
21 to maintain voltage as part of our obligation to
22 serve within certain prescribed limits. This allows
23 us to maintain and continue to do that even with the
24 intermittency and voltage fluctuations introduced by

1 distributed energy resources.

2 That improves the voltage experience for
3 customers and maintains what they experience today.
4 By doing and applying -- doing this work, we're able
5 to support additional DER penetration on the grid as
6 well as what is there today.

7 And then by properly managing voltage, if
8 customers have any concerns about the ability of us
9 to deal with roving electric vehicles or DERs, we'll
10 have this capability there ready for those
11 customers. That will not be part of their concern
12 as they choose to make those kind of choices in the
13 future. And certainly, this helps with two-way
14 power flow of properly managing voltage in that case
15 to prepare the grid for a lower carbon future.

16 So hardening and resiliency. There are
17 three different areas that I talk about in this
18 space. The first of these is laterals. And let me
19 make sure and draw a distinction between laterals
20 and the backbone on the distribution grid.

21 I think you can think of transmission, I
22 think Dan would agree with this, as the interstate
23 highway system is what transmission is. There are
24 super highways and others, but all call them limited

1 access highways.

2 When you think of the distribution grid,
3 think of four lane or urban highways or maybe
4 they're even rural highways, but they're not limited
5 access, and then all the side roads that turn off --
6 that go off of those main roads. The laterals --
7 when you hear me say laterals or tap lines, I'm
8 talking about the side roads. It's the smaller
9 portions of the distribution grid where most of our
10 customers live, but then we'll have also programs
11 that work on the backbone. SOG is an example of one
12 that is focused on the backbone. This particular
13 program, the reason I draw that distinction is it's
14 focused on the laterals.

15 One of the things to keep in mind, if you
16 remember my for-reliability-description early on of
17 not just traditional impacts of reliability but now
18 we're impacting an outage, impacts generation as
19 well as electric vehicle charging. Most of our
20 customers live on and are connected to the grid on
21 the laterals. Many customers are on the backbones,
22 but the vast majority are connected via the
23 laterals. So the lateral reliability takes on a new
24 dimension as we move forward with the grid of the

1 future for that.

2 This is a data-driven approach looking at
3 outage history and very specific cause codes for the
4 outages on those laterals, as well as the review of
5 the physical condition of the wire typically looking
6 for damage or potentially multiple splices when
7 indicating that the line has failed before and been
8 spliced back together.

9 What we most commonly find with this
10 program that needs to be addressed is an older
11 vintage steel core wire. It was a high strength
12 wire, an older, vintage, of material gave us high
13 strength, but over time that steel core that
14 provided the strength presents a corrosion risk.
15 And as that corrosion risk increases, there's
16 potential failure in those particular cases.

17 Our standard -- modern standard now is an
18 all-aluminum high-strength alloy that we deploy in
19 new construction. These laterals would simply be
20 upgraded to our current standards with that
21 high-strength all-aluminum alloy for that.

22 One other comment I'll make here is as I
23 go through the rest of these program summaries,
24 early on, we had programs that were focused on

1 capacity, focused on voltage regulation and then, of
2 course, self-optimizing grid covered three of the
3 four; the rest of these will all focus on
4 reliability. And the reason for that is what I've
5 described, the impacts of an outage now is -- are in
6 the -- now and in the future is also on generation
7 as well as electric vehicles.

8 So the benefits of hardening and
9 resiliency for laterals, reliability and resiliency,
10 eliminating the risk of outages increase the
11 reliability. Improve resiliency. A modern
12 high-strength conductor provides the ability to
13 withstand limbs falling on others that an older
14 conductor with a corrosion risk may not support as
15 easily. And then upgrading historically
16 outage-prone assets lessens the quantity and
17 duration of outages, so overall system resiliency
18 and reliability increases.

19 Any time we avoid an outage that bends the
20 restoration costs curved down for all customers.
21 And then the reliable and resilient grid is
22 certainly necessary for distributed energy resources
23 in the future.

24 And lastly, the benefit cost ratio you see

1 for this of 9.4.

2 So, the second part of hardening and
3 resiliency is public interference. And public
4 interference is a utility term that we use to
5 indicate any time a non-utility worker has impacted
6 the facilities, whether it be just damage or causing
7 an outage. It may be a contractor digging that hits
8 an underground cable. In this particular case, what
9 we're focused on is vehicle accidents where we have
10 cars hit poles.

11 For any of you that watch the news,
12 whether you live in it or just watch the news in one
13 of our metropolitan areas - Raleigh, Charlotte,
14 Greensboro, High Point, and others - likely several
15 times a week during the morning news, either the
16 traffic reporter or some live on-camera reporter is
17 reporting on a vehicle accident that's damaged Duke
18 Energy's facilities, and typically it's broken a
19 pole. There's a large outage in the area and
20 traffic is probably impacted for several hours as
21 they attempt to make repairs in that case. So not
22 only is there the impact to the customers that are
23 actually experiencing the outage, there's societal
24 impacts impacting commerce from transportation and

1 traffic rerouting and other things of that nature.

2 So this particular program, we're focused
3 on those areas where we see with our data now that
4 we've got repeat hits in certain areas. And also,
5 this is focused only on our three-phase, so the most
6 impactful types of events where we have a car hit
7 pole.

8 The solution set would include potentially
9 design change, a relocation of the existing
10 facilities or potentially undergrounding to remove
11 them from the line of fire from particular repeat
12 vehicle accidents in those particular areas.

13 So we'll talk about the benefits. And one
14 of the first things that I'll point out is the
15 benefit cost ratio is less than one, and let me talk
16 about that.

17 So the benefits are reducing or improving
18 reliability and resiliency by relocating facilities,
19 avoiding an event, and making the system more --
20 ability to withstand any kinds of impact. But with
21 the benefit cost ratio, we believe this is prudent
22 utility practice. We've got data that now shows and
23 we can track where vehicle accidents occur on our
24 backbone systems. And there's -- also, as I

1 mentioned besides the pure reliability benefits that
2 go into the cost-benefit ratio, there's the societal
3 benefits and impacts on commerce, and just traffic
4 in general in those particular areas where this
5 occurs frequently in those areas.

6 You'll also notice that overall --
7 compared to the overall MYRP projects that we're
8 proposing, this is less than \$16 million, so very
9 targeted to areas that we see areas for Improvement
10 in that particular space.

11 So distribution hardening and resiliency:
12 Storm, so the last of the hardening and resiliency.
13 This is also a data driven looking at outage history
14 but very specific storm cost codes and also a
15 geographic analysis looking at more of our coastal
16 areas and mountains to look at potential tropical
17 impacts, as well as winter-type weather, icing and
18 others.

19 There's a lot of information there in the
20 program description, but at the heart of it, it
21 talks about Grade B construction and NESC 250B-D
22 loading. What that -- the simple boil-down to that
23 is what that analysis results in is in these areas
24 where we have propensity for higher winds and

1 heavier ice loads is larger and stronger poles,
2 shorter spans between those poles and additional guy
3 wiring to support those structures in the event of
4 high winds and ice loading where we've seen it
5 happen, repeat again and again in those areas.

6 So moving onto the benefits. Again,
7 reliability and resiliency. The grid itself being
8 stronger, able to withstand higher winds and heavier
9 ice loading is the definition of resiliency. Also,
10 by reducing the risk of outages caused by those
11 potential severe weather events we're improving
12 reliability.

13 Outage cost avoidance. Any outage that we
14 prevent bends the cost curve down for all customers
15 from a restoration perspective. And certainly more
16 reliable grid supports additional DER and EV
17 adoption. And you see the benefit cost ratio of 8.7
18 for this work.

19 Distribution Automation. This is an
20 existing program. It modernizes traditional
21 protective devices on our laterals. So again, this
22 is a program focused on the laterals, not the
23 backbone of our distribution circuit, and this is
24 accomplished by replacing a traditional single use

1 fuse with an intelligent electronic device or an
2 automated lateral device. You see an acronym there
3 in the middle. It's really a modern recloser for a
4 single phase device and fits in the same location
5 that a traditional fuse would.

6 I'll share another analogy here. If you
7 think about -- I mentioned your grandparents car and
8 what that -- the modern technologies that it had or
9 didn't have. Think about an older home with a fuse
10 box. Not a breaker panel but a fuse box. And if
11 you lived in a house like that, my grandparents'
12 house had one. When the lights went out in the
13 bathroom or the kitchen, somebody had to go to the
14 back porch where the fuse box was, open the panel,
15 look for the blown fuse. There was probably a box
16 or two or three boxes of different size fuses
17 sitting on the shelf. You unscrewed the other one
18 just like unscrewing a lightbulb. Screw the new one
19 in and the lights came back on, if the fault or the
20 problem was temporary.

21 What I also make sure that I want to say
22 here is that most faults on overhead systems for
23 distribution are temporary faults. A couple of
24 examples: It may be a limb that's falling from a

1 tree, temporarily brushes the line, and continues to
2 fall to the ground, or it may be an incidental
3 animal contact. Those also tend to be temporary
4 faults on the system.

5 The challenge with that traditional fuse,
6 just like the fuse in your grandparents' fuse box,
7 is if the fault is -- magnitude is high enough or
8 it's just long enough, potentially the fuse does
9 what it's supposed to do: It opens up and protects
10 the lines or the circuit from further damage. But
11 it's a temporary fault, so we now have customers
12 that are experiencing sustained outages based on
13 temporary faults.

14 With these automated lateral devices, they
15 can actually reset themselves. So they will sense
16 the temporary fault. They may open up and
17 deenergize the line, but in a couple of seconds they
18 will close back in. And if it truly is a temporary
19 fault, the customer saw a blink, but nobody has a
20 sustained outage at this case. So, that's the value
21 of these devices. You can kind of think about your
22 modern breaker panel that you have in houses of
23 today, but you still have to go out to that breaker
24 panel and turn it off and turn it back on to reset

1 it. These devices do that on their own. There's no
2 human intervention needed.

3 If it is a permanent fault, it will
4 operate and end up staying open and there will be a
5 sustained outage as it should be for a permanent
6 fault. But temporary faults no longer in this case
7 where these devices are deployed cause sustained
8 outages.

9 And again, we talked about reliability
10 being one of those critical key grid capabilities
11 based on generation as well as electric vehicle
12 charge. The benefits of reliability and resiliency
13 again and you see the cost-benefit ratio for this
14 work of 5.1.

15 Equipment retrofit. This is also an
16 existing program. It targets equipment prone to
17 outages caused really by three things: Lightning,
18 overvoltage, clearance issues or animal -- and/or
19 animal interference. And it really upgrades those
20 assets to our modern design, construction and
21 material standards. The types of equipment, I
22 mentioned this earlier that we focus on with this
23 program, are transformers, arrester locations, and
24 riser poles. And remember, riser poles are where

1 our system transitions from overhead to underground.
2 It's that last pole where that transition occurs, is
3 known as a riser pole.

4 The work that we do in these locations is
5 similar in each of the three examples or asset
6 classes. We install, number one, local fuses. That
7 way, if there is a problem at that device, only the
8 customer served by that particular asset experience
9 an outage. Without those local fuses, the outage is
10 further out to the next protected device and
11 customers that don't need to be out, based on that
12 failure, experience an outage right now.

13 We also install animal guards and covered
14 lead wires that mitigates animal interference. And
15 also specifically for lightning arresters, whether
16 they are on a transformer or an arrester station, we
17 replace older vintage porcelain lightning arresters
18 with modern polymer lightning arresters that
19 increases the insulation levels on the distribution
20 lines at those locations.

21 And lastly, we replace conductive metal
22 brackets with non-conductive, typically fiberglass
23 brackets. Again, that helps with clearance issues
24 as well, animal interference, and other clearance

1 issues on those locations.

2 Benefits, like the others, improve
3 reliability and resiliency reducing the number of
4 outages. With those improvements of construction
5 and design standards and materials that we made at
6 those locations, they are able to mitigate animal
7 interference and withstand those contacts without
8 causing an outage. Outage cost avoidance from fewer
9 outages, again for all customers, bends the
10 restoration cost curve down. Certainly improved
11 customer experience for those customers that are
12 served by these assets as they're brought up to
13 modern standards. And lastly, you see the benefit
14 cost ratio for this work of 3.0.

15 Moving on to long duration interruption.
16 This is another existing program, and it relocates
17 segments of our overhead circuits. This is focused
18 on the backbones as opposed to laterals. So this
19 one is again focused on the backbones.

20 And moving those facilities from
21 hard-to-access areas to more truck accessible areas.
22 That certainly reduces outage restoration time and
23 also allows for ease of maintenance to reduce future
24 outage risk when they're easily accessible by

1 mechanized equipment.

2 The targets that show up in this program
3 are typically -- number one, they're typically
4 radial distribution lines that serve either large
5 groups of customers or maybe entire communities that
6 tend to be geographically isolated. And it doesn't
7 make sense for us, from a cost-benefit ratio, to
8 build an alternate feed from another direction
9 because they're isolated geographically. So, the
10 best thing we can do at this time is move those
11 lines from inaccessible areas such as off road,
12 swamps, mountain gorges or other extreme terrain.
13 And they also have typically higher than average
14 outage durations because it's radial and then the
15 lines are inaccessible. It takes our crews longer
16 to respond, find the problem, and make repairs.

17 Then you layer on top of that extreme
18 weather, if these were in a swampy area and we've
19 got a tropical-type of severe weather event, that
20 just exacerbates accessibility, and til we get to
21 that equipment. Same thing in the mountains. If
22 you're in a mountain gorge or an extreme terrain in
23 the mountains and you have an ice and snow event,
24 again because they are not track accessible,

1 extremely difficult to get to. And the solution for
2 these is really to move those to road right-of-way
3 or truck accessible areas.

4 The benefits, similar here, reducing those
5 outage risks. So reliability, resiliency, bending
6 down the outage cost curve by reducing the number of
7 outages that occur. And also more shorter outage
8 durations in those extreme events or when they do
9 have one because it is truck accessible.

10 This not only bends the cost curve down
11 for outages that don't occur, but the cost of
12 restoring in those extreme terrain areas typically
13 is much more manpower than traditional, very
14 specialized equipment to get in there, and we can do
15 that -- if we move those to road right-of-way we can
16 leverage our standard equipment and access from the
17 roadway and repair much quicker in those cases.

18 You also see the benefit cost ratio of
19 14.0 for this particular body of work.

20 Targeted underground. Another existing
21 program. This one is also data driven. This one
22 focuses on our laterals, so back to the lateral
23 parts of our system. Strategically identifies in
24 undergrounds the most outage-prone overhead line

1 segments. This reduces not only the outages for
2 those customers served by those line segments, but
3 once we've undergrounded those, they typically are
4 in heavily vegetated areas in rear lot. It
5 eliminates that vegetation management cost in the
6 future when those lines are placed underground.

7 The attributes that typically show up for
8 these targets of unusually high outage frequency.
9 The location of the lines currently is typically
10 rear lot built behind houses and inaccessible to
11 mechanized equipment. And typically over the years
12 those have become heavily vegetated even if they
13 weren't when the lines were originally built. And
14 the solution for these is to move those to the road
15 right-of-way or front lot and also underground those
16 lines as well.

17 Also, for this program, no surprise,
18 reliability and resiliency are key by putting lines
19 underground. Certainly less susceptibility to
20 weather impacts at least in major events and normal
21 storms. We've also eliminated, as I said earlier,
22 that vegetation management cost and also the
23 restoration cost. Those lines are much easier to
24 access and restore being moved to the front lot

1 line. Again, we don't have non-mechanized outage
2 restoration happening behind homes. And again, the
3 laterals are where the majority of the EVs and
4 distributed energy resources will show up as we move
5 into the future. So that lateral reliability is
6 even more important. And lastly, you see a benefit
7 cost ratio of 7.0 for this work.

8 So hazard tree removal. And then I'll
9 finish with infrastructure integrity. Hazard tree
10 removal. And I described this earlier, but I want
11 to reiterate this is part of our integrated
12 vegetation management program. One portion is
13 focused on vegetation management within our
14 prescribed rights-of-way. An example may be a
15 30-foot right-of-way for distribution lines so our
16 lines are in the center and we maintain 15-feet
17 either side of those facilities. This work is not
18 focused inside the right-of-way. It is very
19 specifically and limited to the outside the
20 right-of-way. And what our specialists are looking
21 for is dead, diseased, dying or otherwise
22 structurally unsound trees that if they fail they
23 fall toward the distribution lines and cause impacts
24 to our system. And I'll also say vegetation within

1 the rights-of-way typically is smaller vegetation.
2 It's limbs falling, et cetera.
3 Many times, it doesn't actually damage our
4 facilities, it just causes an outage, but at most it
5 typically would just break the wire.

6 You have a tree falling from outside the
7 right-of-way, it is not only going to take the wire
8 down, it likely is breaking a pole or multiple poles
9 that now have to be replaced so we have
10 infrastructure replacement to do before we can even
11 begin restoration in those cases. And to talk about
12 the impact of trees from falling outside the
13 right-of-way: for DEP North Carolina, the last five
14 years, 2017 through 2021, every single year more
15 than 50 percent of our vegetation outages were from
16 trees falling from outside the right-of-way in that
17 case. So heavily impactful from that. And again,
18 this is all outside of our right-of-way.

19 The way we accomplish this work, a Duke
20 Energy representative specializing in vegetation
21 practices leverages an industry best practices to
22 identify those dead, diseased, or dying, or
23 structurally unsound trees. If they do discover an
24 extreme risk to infrastructure that is in imminent

1 failure, they will assign that to a vegetation
2 supplier to immediately take that tree down, but the
3 vast majority will result in a list of hazard trees
4 in locations presented to one of our vegetation
5 suppliers. They make contacts with the customer,
6 explain the work, receive consent, and then schedule
7 to take those trees down on a particular schedule.

8 And the benefits for this, again, reduces
9 the risk of outages. And I described how impactful
10 that has been over the last five years for DEP North
11 Carolina from those trees falling from outside the
12 right-of-way. This is a prudent utility practice
13 and has been. We've been doing this for years to
14 remove those threats that we identify outside the
15 right-of-way as well as properly maintaining those
16 inside the right-of-way.

17 And lastly, infrastructure integrity. I
18 talked about this a little bit earlier but back to
19 that house analogy. All the other programs I've
20 described are doing -- they're more like the house
21 remodel. They're looking above the ground. It's
22 the things that we need to add to the grid and
23 improvements we need to make there, but we also have
24 to look at all of the infrastructure that's served

1 or part of these MYRP projects and make sure the
2 foundation is in good condition. Same thing for
3 that remodel. You wouldn't do all or spend all
4 those dollars to improve everything above the ground
5 if you've got a failing foundation or problems that
6 need to be addressed before doing that work.

7 Some examples of this you'll see in the
8 bottom, in the program description. That would
9 include inspection-based asset replacements. It
10 could be transformers that have been inspected as
11 well as poles. Oil mitigation where we have
12 opportunities to upgrade equipment from hydraulic to
13 solid di-electric removes oil off the system.
14 Distribution does have some SF6 gas insulated switch
15 gears. Those are typically vault-mounted switch
16 gear that we now have the option to replace with
17 modern solid di-electric so we can remove that SF6
18 gas from the distribution grid.

19 Technological obsolescence, that's one
20 that's listed there. That one specifically say
21 recloser controls, but that could also apply to
22 regulator or capacity or other electronic devices on
23 the distribution grid that have a control panel.
24 And the obsolescence could be a couple of things or

1 multiple things. It could be one that doesn't fit
2 our cyber security requirements now. It could also
3 be one that the vendor is no longer supporting.
4 It's actually functioning, but if it fails, we can't
5 find parts or do any replacement and so we've
6 upgraded that to a modern. Or the example I gave
7 earlier, technological obsolescence for voltage
8 regulators. The current controls cannot control
9 voltage in two different directions. They are
10 simply looking from the substation out to control
11 voltage. The modern controls can determine a stiff
12 source from either direction and properly maintain
13 voltage. And there's a couple of other examples
14 also.

15 And lastly, the benefits for
16 infrastructure integrity, again, reliability and
17 resiliency, it reduces the risk of outage due to
18 unplanned replacements or failures. Sustained
19 infrastructure integrity enables more efficient
20 restoration when there is an event that we need to
21 deal with -- oh, sorry. I lost my train of thought
22 there for a second -- also for the customers and the
23 experience. Having planned replacements of these
24 assets is much less impactful than unplanned events,

1 whether it be an outage or doing those individually.
2 We do those as part of our overall MYRP projects.
3 As I stated earlier, we mobilize in -- uplift the
4 infrastructure, including this work, and then move
5 on to the next area.

6 That concludes the distribution projects.
7 I'll now turn it over to Dan Maley to talk about
8 transmission projects.

9 CHAIR MITCHELL: Why don't we pause here
10 and let me check in with Commissioners to see if
11 there are questions for Mr. Guyton on his
12 presentation. Commissioner Clodfelter, go ahead.

13 COMMISSIONER CLODFELTER: I have several
14 questions but they're not specific to distribution.
15 But, Mr. Guyton, I've got one for you that is
16 specific to distribution, and let me preface the
17 question with a comment. Way back in the dark ages,
18 before the pandemic, I remember the Technical
19 Conference at which you came at and presented the
20 plans for ISOP, and I wanted to just say to you that
21 listening today, to some of what you went through,
22 is a really good feeling to see what's come to
23 fruition over the course of the last three years as
24 you've implemented the ISOP initiative, and to see

1 some of the fruits of that today is good. I
2 appreciate it. I remember when you were just
3 starting the journey, and it's good to see the
4 progress you've made along the way.

5 The question really relates to the
6 capabilities of MoreCast and how it works. And I'm
7 really intrigued about how, when you're, sort of,
8 running a MoreCast, a forecast of a circuit and try
9 to identify, sort of, the three to five-year needs
10 on that circuit for various investments on the
11 circuit. You tell me if I'm wrong, but I'm assuming
12 that within forecast, within MoreCast you're not
13 able to model endogenously within MoreCast the
14 adoption rates of EVs on a particular circuit or
15 installation of rooftop solar or other DERs on that
16 circuit or that substation. MoreCast can't do that
17 modeling, can it?

18 MR. GUYTON: There are some -- good
19 question. There are some assumptions made. And I
20 don't know the absolute details of the algorithm,
21 but it does look at certain factors that an area
22 would be more prone to adopt EV or rooftop solar.
23 Again, I don't know the gory details of that, but it
24 does assume based on customers and other things of

1 who might be and what areas might be more prone to
2 adopt faster in those cases.

3 COMMISSIONER CLODFELTER: Well, that's
4 intriguing because that's really -- well, you're
5 getting at the heart of really what I wanted to
6 explore was whether or not you provide, sort of, a
7 certain level of EV adoption and a certain level of
8 rooftop solar within the service area of a given
9 substation and just provide that as an external
10 input to MoreCast and then say solve for that level
11 of DER and EV adoption, or whether the model itself
12 can generate some of that.

13 MR. GUYTON: So my understanding is there
14 are multiple data inputs into the model that -- then
15 it calculates what that propensity to adopt EV or
16 solar is as opposed to just having a -- here's an EV
17 number or here's a DER number from that. But I
18 don't know the detail specifics of the algorithm
19 that does that.

20 COMMISSIONER CLODFELTER: Wow. That's
21 really interesting to hear. And so at least a
22 follow-up question which is do you then feed those
23 results upstream to the resource planners and say,
24 "Look, we're a -- when we run MoreCast across the

1 distribution grid, we're seeing this rate of EV
2 adoption and you should expect this many EVs on the
3 grid within five-years time". Do you share that
4 information with the resource planners?

5 MR. GUYTON: Yes. And actually, MoreCast
6 is part of truly the ISOP tool set, so it's part of
7 ISOP. The planning engineers actually leverage that
8 for load forecasting for an individual circuit, so
9 it's actually -- the critical part of it is to
10 inform the overall Integrated Resource Plan. We're
11 leveraging, like I said, the first five years of
12 that forecast to look at actual planning for
13 distribution projects that -- infrastructure
14 projects that need to be executed.

15 COMMISSIONER CLODFELTER: Outstanding.
16 So, let me ask the ultimate \$64,000 question. So
17 when I read the IRP or the Carbon Plan, which we're
18 currently reading, either one of them, when I read
19 those documents and I see sort of a projection of
20 how much rooftop solar is going to be out on the
21 grid over the course of the planning period, I can
22 say that's an output. In large measure, it's an
23 output from the MoreCast forecasting process?

24 MR. GUYTON: I was not part of the Carbon

1 Plan development, et cetera. That would be by
2 assumption, but it would need to be validated, but I
3 would expect that.

4 COMMISSIONER CLODFELTER: That's very
5 interesting. Thank you for that. That's very
6 helpful. That's my question. Thank you.

7 CHAIR MITCHELL: Additional questions?
8 I'm unable to see Commissioners Duffley, Brown-Bland
9 and Hughes, so if you-all have questions, you need
10 to let me know because I can't see you right now.

11 COMMISSIONER DUFFLEY: I have a question.
12 It's Kim Duffley.

13 CHAIR MITCHELL: Okay. Go ahead,
14 Commissioner Duffley.

15 COMMISSIONER DUFFLEY: So you may hear
16 from other Commissioners asking about SAVe and SAFe,
17 but in the presentation I heard a lot of benefits
18 regarding reducing outages as well as the length of
19 the outages. And so my question is what are your
20 current SAVe and SAFe metrics right now compared to
21 your past two rate cases and, you know, generally
22 are they trending up or down?

23 MR. GUYTON: Commissioner, off the top of
24 my head, I don't have that information in front of

1 me. I think they're -- I can -- specifically for
2 self-optimizing grid, that has a substantial impact
3 on reliability. There's a lot of other impacts so I
4 don't know the overall system numbers and how those
5 are trending at the moment, but the impacts of -- if
6 just as an example, for the self-optimizing grid
7 work that we're proposing to execute in this time
8 period, we expect -- I'm sorry, I'm looking. I have
9 a number here that I had captured for this
10 purpose -- an additional 21 million customer minutes
11 of interruption saved just for the self-optimizing
12 grid work that we're proposing in this MYRP plan.
13 So I apologize for not having the rivalry numbers
14 tied to the rate case time periods, but quite a bit
15 of this --

16 COMMISSIONER DUFFLEY: That's okay. We
17 can find them. I just wondered if you knew off the
18 top of your head while we're talking about it today.
19 So thank you for that answer.

20 And then my one other question is when you
21 went over the infrastructure integrity program
22 overview and benefits, and you may have said this
23 and I missed it, but all the -- most of the other
24 ones have the total benefits, you know, gave that

1 benefit cost ratio, and this program did not have
2 that. And what is the reason for not having it with
3 this program?

4 MR. GUYTON: Yeah, thank you for asking.
5 So infrastructure integrity is work that we -- we
6 see that as an obligation to serve as a utility to
7 maintain the foundation, whether we're doing other
8 reliability improvements and things above the norm.
9 This is simply maintaining that foundation. And so
10 I guess the example I would give is if I have --
11 kind of back to my analogy earlier -- if I'm going
12 to do that house remodel but I've got a
13 foundational, foundation issue, I certainly may get
14 different bids from vendors, but I'm not going to
15 not fix the foundation. It's just work that I have
16 to do from that perspective. I wouldn't do a cost
17 benefit of, okay, if the foundation fails, here's
18 what will happen versus spending the money to fix
19 it. I'm going to fix it from that perspective. So
20 that was the reasoning there.

21 COMMISSIONER DUFFLEY: Okay. That makes
22 sense. Thank you. I have no further questions.

23 MR. GUYTON: Thank you.

24 CHAIR MITCHELL: Additional questions?

1 Commissioner McKissick.

2 COMMISSIONER McKISSICK: Sure, just one or
3 two. In looking at your cost-benefit ratio, of
4 course it varies from project to project. Some may
5 be down at 0.5 percent and others up at 8.1. What
6 methodology that you use for establishing the
7 cost-benefit ratio for these particular projects?
8 And I guess that question also applies to ones that
9 we're going to get into later in the next session of
10 the presentation. Could you be -- could you
11 elaborate further on the methodology that was used?

12 MR. GUYTON: Absolutely. So I would offer
13 overall we leveraged a similar methodology as we
14 have in the past.

15 COMMISSIONER McKISSICK: Okay.

16 MR. GUYTON: And at the core of that is
17 the ICE calculator, Interruption Cost Estimating
18 tool. Based on feedback from this Commission and
19 staff previously from those other filings, we not
20 only use the ICE calculator, but also specifically
21 using the online version, created our tables
22 specific for North Carolina as opposed to the
23 standard tables that are part of the ICE calculator.
24 And those went into our traditional cost-benefit

1 analysis tools of here's all the costs we have,
2 here's the benefits, not only from the ICE
3 calculator but our cost to restore the outage, and
4 under their factors such as that.

5 COMMISSIONER McKISSICK: So is the ICE
6 calculator and specifically the ratios applicable to
7 North Carolina?

8 MR. GUYTON: That's correct. We
9 generate -- from the online tool you can go in and
10 actually pick the state -- I can't remember the
11 other criteria that's there -- and actually, it will
12 generate value that then we specifically took those
13 values and put them into our CBA analysis tools
14 that --

15 COMMISSIONER McKISSICK: Thank you. Did
16 you consider employing or utilizing any other tools
17 or methodologies for calculating the cost-benefit
18 ratios?

19 MR. GUYTON: Not that I'm aware of. The
20 ICE calculator is the only one that I'm personally
21 aware of that's an industry-accepted. It was funded
22 by the DOE. They're going through some updates I
23 think to the tool now that we will probably see
24 maybe in 2024 or 2025, including more utilities,

1 different surveys, and updated data from that. So,
2 that's the only one that I'm aware of. But that is
3 what we use, sir.

4 COMMISSIONER McKISSICK: Sure. Thank you.
5 And I guess the other question is kind of a follow
6 up to what Commissioner Clodfelter asked you.

7 The thing I'm trying to determine when
8 you're looking at say adoption of EVs or adoption of
9 rooftop solar. At least for rooftop solar, we have
10 a pretty long established track record for the EVs.
11 It's not so great. How do you sit back and
12 extrapolate what that adoption rate might be,
13 particularly since it could be linked to other
14 external factors that you may not have control over,
15 like the price of a barrel of oil.

16 MR. GUYTON: Good question. And I guess
17 I'll have to answer it the same way I answered
18 Commissioner Clodfelter's question, is I don't know
19 the details, but it does look at multiple factors
20 and incorporate those of what may drive someone to
21 select an EV. I don't know if it looks at economic
22 data of household income and other statistical
23 information, but leverages that to look at both
24 historically where you've seen DER adoption, what

1 tended to be the drivers there. And I think they're
2 making some assumptions, of course, and trying to
3 bottle what do we think the EVPs will be like, based
4 on the best data that we have from that perspective.

5 COMMISSIONER McKISSICK: Thank you.

6 CHAIR MITCHELL: Commissioner Clodfelter.

7 COMMISSIONER CLODFELTER: Let me follow a
8 little bit on one of the questions that Commissioner
9 McKissick asked you. I was going to hold it til the
10 end because it applies to transmission as well, but
11 since we've got the topic on the table, let me go
12 ahead and ask it.

13 In the last -- the Company's last general
14 rate case, Public Staff witnesses Thomas and
15 Williamson and a couple of the Intervenor witnesses
16 made some very detailed recommendations about how
17 Duke should revise and adjust its cost-benefit
18 analyses, changes to data sources and inputs, as
19 well as changes to methodologies. Other than what
20 you outlined to Commissioner McKissick, what other
21 responses did the Company make to those suggestions
22 from the Public Staff witnesses?

23 MR. GUYTON: Besides the one I
24 specifically referenced of that very specific North

1 Carolina table, I personally do not know what those
2 changes may have been. I know there was a lot of
3 discussion and intake of that into looking at how we
4 would modify those. But that's the one I
5 specifically know of. I'm not saying that others
6 weren't done or addressed, but I do not know the
7 answer to that question.

8 COMMISSIONER CLODFELTER: I predict that's
9 going to be a topic of some questions in the rate
10 case themselves, and so it's good to go ahead and get
11 the question on the table for you today so everybody
12 can be thinking about it.

13 Let me ask you about one specifically and
14 see if it jogs your recollection. The Public Staff
15 suggested that the Company run sensitivities to
16 various -- to different variables using the
17 cost-benefit analyses and that that was not done in
18 the last series of studies that were presented in
19 the last rate case. Do you know if in the current
20 modeling of cost-benefit analysis that you've got
21 summarized in these materials where the different
22 sensitivities were ran -- were run on different
23 variables?

24 MR. GUYTON: I do not know for sure.

1 COMMISSIONER CLODFELTER: Don't know?

2 MR. GUYTON: No.

3 COMMISSIONER CLODFELTER: Okay. Again,
4 I --

5 MR. GUYTON: We did not run multiple
6 cost-benefit analyses for sensitivities.

7 COMMISSIONER CLODFELTER: Okay. Just
8 forecasting questions for the general rate case.

9 MR. GUYTON: Absolutely.

10 COMMISSIONER CLODFELTER: Trying to help
11 you guys out. That's all.

12 CHAIR MITCHELL: Commissioner Kemerait.

13 COMMISSIONER KEMERAIT: Thank you for your
14 presentation. Just following up on Commissioner
15 Duffley's question. In addition to the
16 infrastructure integrity program, I also did not see
17 a benefit-cost ratio for the hazard tree removal
18 program. Is there a reason why that program also
19 does not have the ratio?

20 MR. GUYTON: Great question. And really
21 it's the same answer. This is an obligation to
22 serve. We have a known threat to infrastructure and
23 the trees need to be removed.

24 And I guess another analogy I would give

NORTH CAROLINA UTILITIES COMMISSION

1 is if I've got a tree leaning over my house that's
2 posing a threat - it's dead, dying, or an arborist
3 tells me it's dead, dying or structurally unsound -
4 I certainly may get bids from competitive vendors to
5 take it down and choose the one I think is
6 appropriate, but it won't be a cost-benefit analysis
7 if I don't do anything versus doing anything. It's
8 a known risk that we -- we see that as obligation to
9 serve.

10 COMMISSIONER KEMERAIT: Thank you.

11 CHAIR MITCHELL: Commissioner Brown-Bland,
12 I see you on camera. Do you have a question?

13 COMMISSIONER BROWN-BLAND: No, no
14 question.

15 CHAIR MITCHELL: Mr. Guyton, I have a few
16 for you. We'll stick with hazard tree removal since
17 Commissioner Kemeraut was just talking to you about
18 it. How does what you-all have proposed here are
19 compared to what you-all are currently doing with
20 respect to hazard tree removal?

21 MR. GUYTON: We're removing hazard trees
22 now. This is simply --

23 CHAIR MITCHELL: A continuation of --

24 MR. GUYTON: -- a continuation of that

1 work. We feel like it meets the requirements for
2 inclusion in MYRP. But it is the -- I mean, the
3 process and what we do and how we do it is exactly
4 the same.

5 CHAIR MITCHELL: Okay. And level of
6 spending would be similar to what you're spending
7 now?

8 MR. GUYTON: To my knowledge, yes. We're
9 doing that work now.

10 CHAIR MITCHELL: Okay. And did I hear you
11 correctly, if I didn't correct me, when you said
12 50 percent of vegetation management-related outages
13 caused -- that the Company is experiencing now are
14 caused by trees from outside the right-of-way?

15 MR. GUYTON: That is correct.

16 CHAIR MITCHELL: Okay.

17 MR. GUYTON: And that's not just the
18 average over the last five years. Every single one
19 of those five years, it is above 50 percent. It
20 moves from, I think it was 51 to 56 percent, but
21 consistently it is over half of the vegetation
22 outages.

23 CHAIR MITCHELL: Okay. You also discussed
24 today, with respect to the capacity program, outages

1 due to overloaded conductors. Is the Company
2 experiencing overloaded conductors from associated
3 with DER penetration or customer load at this point
4 in time or is that -- or is the Company anticipating
5 that?

6 MR. GUYTON: Is the question are we
7 experiencing overloads or are we experiencing
8 failures due to overload?

9 CHAIR MITCHELL: Well, overloaded
10 conductors.

11 MR. GUYTON: By our planning analyses,
12 there are conductors that are technically
13 overloaded.

14 CHAIR MITCHELL: At present, there are
15 overloaded conductors?

16 MR. GUYTON: At present. Specifically, I
17 couldn't tell you or give you a specific example of
18 this one is overloaded because of DER, but we are
19 constantly looking at thermal overloads and then
20 addressing those appropriately; whatever the drivers
21 are.

22 CHAIR MITCHELL: Okay.

23 MR. GUYTON: In capacity and in our
24 forward-looking capacity we are, as the other

1 questions have come about MoreCast and how it views
2 EV adoption and DER, we are looking to create
3 additional headroom or hosting capacity on those
4 circuits and not get to an overload situation, even
5 with EVs and DERs coming from that perspective. So
6 that's the -- you know, if traditional planning was
7 here, there's another layer of capacity here
8 (indicating) to be able to deal with those modern
9 technologies and their impacts.

10 CHAIR MITCHELL: Okay, thank you for that.
11 Some of the -- as I have understood what you-all
12 have -- what you've described today, some of these
13 programs would seek to prevent faults and some of
14 them would seek to mitigate the impact of faults.
15 You've described the self-optimizing grid would
16 mitigate the impact of faults on, you know,
17 customers on the circuit. So, how do you-all
18 prioritize spending on programs that prevent fault
19 versus mitigate impacts of fault?

20 MR. GUYTON: So, what I would offer is
21 that what we're proposing here is a comprehensive
22 plan so we're addressing both. It's an "all of the
23 above". One, we need to make sure that we can
24 never -- we can never build a grid that would never

1 have a fault. That's not a practical thing to do or
2 couldn't afford it even if we could do it and so we
3 address both. Certainly, the intent is wherever we
4 have identified ways to prevent faults and do that
5 with a cost-benefit analysis, make sure it's worth
6 the money to do, we're going to try and prevent the
7 fault first. If there's not a way to simply prevent
8 the fault from ever occurring, let's make sure we
9 minimize the impact to many customers, and that's
10 why what you'll see is on the laterals. It tends to
11 focus more on fault elimination or trying to prevent
12 it from being an outage; whereas, on self-optimizing
13 grid, we know we're going to have those things
14 impact significant numbers of customers, and so they
15 are -- while we still do work to try and prevent the
16 faults - vegetation management - a lot of the
17 equipment retrofit work, that will be on laterals
18 and backbone circuits. Wherever that equipment
19 exists, that's where we would apply that and that is
20 fault. Trying to eliminate faults as opposed to
21 just preventing the impacts. So I'm not sure if I
22 answered your question.

23 CHAIR MITCHELL: You did. The Commission
24 in the most recent rate case orders directed the

1 Companies to work with -- I think it was at Vote
2 Solar's request. Let me get my notes. It's Vote
3 Solar. A stipulation that Duke entered into with
4 Vote Solar to form a Climate Risk and Resilience
5 Working Group to identify vulnerabilities on the
6 grid and potentially solutions for those
7 vulnerabilities that result from severe weather
8 impacts. Is any of this work informed by the work
9 of that group, to your knowledge?

10 MR. GUYTON: So, I'm going to say no, but
11 let me preface this with this. My understanding of
12 that Climate Risk and Resiliency Study is looking
13 further out in the future for threats into the
14 future. And then once those threats are identified
15 with that, I guess the first part of that study,
16 then what would potentially be changed in design
17 standards or other things for that decades-out look,
18 and so this work is focused on what we know now and
19 what we do so. I'm going to say I'm not aware of
20 any --

21 MR. BROWN: I can add, too, that I've seen
22 a draft report of that. I think it's going to be
23 issued very soon that the work that we have
24 contemplated in for T&D is not counter to anything

1 that's going to be found within at least the initial
2 inputs from that particular study.

3 CHAIR MITCHELL: Okay. How are you -- are
4 you-all assessing weather-related risks the same way
5 for the purposes of this nearer-term activity versus
6 perhaps the longer-term analysis that the Climate
7 Risk and Resilience Group is undertaking?

8 MR. GUYTON: I'm not sure I'd answer that
9 with a yes, but what I will say is that that storm
10 hardening resiliency that I just spoke of,
11 recognizing the frequency and severity that we have
12 of both winter and tropical events now, is looking
13 very specifically at those areas that we've seen
14 impacted repeatedly in the past and then applying
15 Grade B construction and NESC-D -- NESC ice loading
16 criteria for those. I would not be surprised if in
17 that climate study at some point it references
18 higher standards of strength for the grid because of
19 future threats for that. So I think, as Justin
20 said, it's in line with where we believe that study
21 will go, you know, strengthening the grid. And so I
22 don't see that being counter to it, I think it's
23 supportive. We're out in front of it, again,
24 looking at severe weather impacts.

1 CHAIR MITCHELL: Okay. And so as you --
2 to identify severe weather impacts or severe weather
3 risks to DEP's grid, what data are you relying on?
4 How are you analyzing that?

5 MR. GUYTON: So it is looking at the
6 locations where we've had previous damage from
7 tropical events as well as winter events, and
8 looking specifically at the outage-caused codes. If
9 it's a storm outage-caused code, the dates line up
10 with when we had one of those major events because
11 those typically are major event days. We had that
12 data to look at and say where do we see damage?
13 Let's assess those areas and see if it needs
14 additional strength for ice loading or high winds
15 from tropical events.

16 CHAIR MITCHELL: Thank you. That helps
17 me. Several Commissioners have asked you about
18 benefits, program benefits. You've discussed them
19 at length here today. In some cases they've been
20 quantified. The more -- I'm curious and ready to
21 learn more about how the Company is identifying
22 benefits and quantifying them. So, the more that
23 the Company can help me, as a Commissioner,
24 understand that, how you're identifying benefits and

1 quantifying them, would be much appreciated.

2 MR. GUYTON: Okay.

3 CHAIR MITCHELL: That was a comment more
4 than a question. Let me just look through here and
5 see if there's anything else I want to ask you.

6 Maximum ambient temperature. Is there
7 a -- is the distribution system designed to maximum
8 ambient temperature for optimal operation at this
9 point in time?

10 MR. GUYTON: I know that in our conductor
11 ratings, air temperature is taken into account. I
12 don't know if they look at maximum ambient or not.
13 I'm not a standards engineer.

14 CHAIR MITCHELL: Understood.

15 MR. GUYTON: There is temperature, you
16 know, variations based on sag because that's how we
17 develop our spacing all on the poles.

18 CHAIR MITCHELL: And do you anticipate
19 that changing ambient line ratings or your taking
20 into account of temperature ranges?

21 MR. GUYTON: I would think that a climate
22 resiliency study is going to point to things of that
23 nature. If they truly are identifying a change in
24 temperatures, that would be incorporated, because we

1 would assume our normal temperatures are greater.

2 But I --

3 CHAIR MITCHELL: Well, I don't
4 necessarily -- I mean, for purposes of your
5 operations, allowing your, sort of, greater
6 temperature fluctuations for purpose of your
7 operations.

8 MR. GUYTON: I do not know, but I would
9 think that would be taken into consideration both
10 for operational practices as well as design
11 standards.

12 CHAIR MITCHELL: Okay. So, it's not
13 something that you-all are considering right now is
14 what I'm taking --

15 MR. GUYTON: It is not part of the -- that
16 we are leveraging for this work, our current design
17 and construction standards for this work.

18 CHAIR MITCHELL: Okay. And one last
19 question for you and this is mostly to make sure I
20 am reading this correctly. Back to the hazard tree
21 removal program. Are you-all proposing to
22 capitalize certain expenditures associated with that
23 program?

24 MR. GUYTON: Work outside the right --

1 work inside of our maintained right-of-way is O&M
2 costs to maintain that. Doing work or expanding --
3 not really expanding the right-of-way -- doing
4 outside is capitalized. I'm not an accountant but
5 that's my understanding of how that work is treated
6 outside the right-of-way versus inside.

7 CHAIR MITCHELL: So to the extent that
8 these costs are shown as capital costs would be due
9 to the fact that work is being conducted outside the
10 Company's --

11 MR. GUYTON: Correct.

12 CHAIR MITCHELL: Okay. Go ahead,
13 Commissioner Clodfelter.

14 COMMISSIONER CLODFELTER: Mr. Guyton,
15 sorry I didn't think of this earlier. I apologize.
16 With respect to the LDI program, I'm reminded that
17 one of the justifications or the principal
18 justification for the Hot Springs microgrid was to
19 solve an LDI problem, but I don't see that
20 identified as one of the options for the LDI
21 program. Should I draw any conclusions about the
22 success or failure of the microgrid at Hot Springs
23 or is there some other reason why that's not an
24 element or a potential option for dealing with LDI

1 situations?

2 MR. GUYTON: I don't think that should be
3 taken as any reflection on Hot Springs. Things I've
4 heard and seen from that, I'm not keyed on that
5 project, but things are moving along appropriately
6 for it.

7 In this particular case with -- I think
8 Hot Springs had some unique abilities to take on
9 that type of project. But certainly, as we look at
10 capacity or other upgrades like that, a non-wires
11 alternative is part of our analysis in that.

12 For the long duration interruption, it
13 typically is not like a Hot Springs where you've
14 got -- I don't remember the number of customers, but
15 that whole little village was impacted. These tend
16 to be smaller but they're the customers that see
17 those every time we have a major event or there's an
18 outage, even in blue sky days. It's long to get to
19 them and get them restored just because of the
20 access to the lines. Hot Springs had that
21 challenge, too. It was remote terrain at Hot
22 Springs.

23 COMMISSIONER CLODFELTER: So again, help
24 me understand why that would not be one of the

1 weapons in your arsenal for solving long duration at
2 Hot Springs?

3 MR. GUYTON: I think it certainly could
4 be. But for these, the cost of being able to
5 relocate to the roadway was much cheaper than
6 battery alternatives for these on those.

7 COMMISSIONER CLODFELTER: So these are --
8 we look at these as low-cost solutions?

9 MR. GUYTON: They're low cost. And I
10 would offer -- I'd have to go back and look at the
11 projects, but the number of customers impacted is
12 much less.

13 COMMISSIONER CLODFELTER: Is much less
14 than in the Hot Springs case.

15 MR. GUYTON: Yeah, Hot Springs.

16 COMMISSIONER CLODFELTER: So do you --
17 where would I look if I wanted to look in here and
18 just find where you're going to address similar
19 situations or opportunities, I should call them,
20 like the Hot Springs opportunity. Which program
21 would sort of speak at --

22 MR. GUYTON: That would actually be in
23 capacity. So, if we have --

24 COMMISSIONER CLODFELTER: In capacity.

1 MR. GUYTON: If we have capacity projects
2 where traditionally we would propose a wires
3 alternative, so typically upgrading wires or
4 equipment, that's where we would do a non-wires
5 alternative review for that. We've done some of
6 those. We haven't had one that that was the
7 least-cost opportunity or option to do those, but
8 we're continuing to do those. And I would expect
9 over time if costs moderate after the global
10 uncertainties in those spaces, that you would see
11 those start to move into that space.

12 COMMISSIONER CLODFELTER: Okay.

13 MR. GUYTON: But we are constantly
14 leveraging our Energy Storage Group looking for
15 places to deploy additional battery-type assets.

16 COMMISSIONER CLODFELTER: Thank you, sir.

17 CHAIR MITCHELL: Last question from
18 Commissioner McKissick.

19 COMMISSIONER McKISSICK: And this is just
20 kind of a more of a curiosity than anything else. I
21 noticed in the distribution hardening and resiliency
22 Program, it refers to you planning on using,
23 assuming a Grade B, and NESC standard 250 BA. Why
24 did you decide to use that as the standard as

1 opposed to whatever Grade A would have been?

2 MR. GUYTON: So I'm not a standards
3 engineer, but my understanding of that is, that is a
4 higher level of strength --

5 COMMISSIONER McKISSICK: Okay.

6 MR. GUYTON: -- grade B, than what our
7 typical construction is. And in the NESC loading
8 criteria, I think it was 250B-D, that's actually
9 looking at ice loading, and that's looking at --
10 that's -- which our historical grid we have not had
11 that type of activity. We've always had some ice,
12 but they're getting more severe. A heavier
13 application of ice, so that's why we're looking at
14 those areas and saying let's move up to a higher
15 level of strength in those areas, whether it be for
16 ice loading or wind loading, and that's what those
17 are addressing.

18 COMMISSIONER McKISSICK: So I take it that
19 what you're doing is improving the standards that
20 have been historically utilized, perhaps not going
21 completely to a point where it may not be cost
22 beneficial to go to that extra level of improvement?

23 MR. GUYTON: That is correct. And we're
24 also targeting specific areas, so that wouldn't just

1 be changing distribution standards to go all Grade B
2 construction everywhere. It's, hey, where do we
3 actually have high wind loadings, so we'll look at
4 those coastal areas, again, looking at our data
5 where we've had structural damage from high winds in
6 previous storms, and then looking for opportunities
7 to make those changes to the --

8 COMMISSIONER McKISSICK: Can I take in
9 prioritizing those areas, do you look at service
10 interruptions or problems that have occurred in the
11 past? Is it that typically historical data?

12 MR. GUYTON: It is the number of customers
13 that are served. And once we've made those
14 improvements, what would the benefits be, and
15 leveraging those that are the highest benefits in
16 those areas.

17 COMMISSIONER McKISSICK: Thank you.

18 CHAIR MITCHELL: At this point, we're
19 going to take a short break for the court reporter.
20 We will have a recess and we will come back on the
21 record at four o'clock. Thank you.

22 (A recess was taken)

23 CHAIR MITCHELL: All right. Let's go back
24 on the record, please.

1 Mr. Brown, y'all may continue.

2 MR. BROWN: Thank you. Mr. Maley?

3 MR. MALEY: All right. Good afternoon.

4 I'm Dan Maley. I'll be speaking to our transmission
5 projects.

6 We are going to start off with an overview
7 of the project areas, and then I'll be drilling down
8 into some specific project locations. One thing
9 I'll mention off the bat is you will notice some
10 similarities between the distribution programs that
11 Mr. Guyton spoke of and the transmission projects
12 that I will speak of. Some of the terminology is a
13 little bit different whereas distribution is
14 arranged in terms of programs and projects in
15 transmission. Portfolios are arranged in terms of
16 seven unique transmission projects. And then result
17 in project locations where we are actually
18 implementing the work. I will talk through some of
19 the details there.

20 The commonality really between the two is
21 we are both bundling work in common geographic areas
22 to most effectively and efficiently plan and design
23 and schedule and implement the ultimate work.

24 I'll start off by describing some of the

1 characteristics that will be enabled by the
2 transmission project areas. System intelligence,
3 the first category here, we're really improving grid
4 awareness for our grid operators and engineers
5 through the installation of intelligent field
6 devices that get more information back to our
7 operators so they can make smart decisions about
8 manipulating the grid restoring customers.

9 Our hardening and resiliency projects
10 similar to what you heard for the distribution
11 system. We are targeting a more -- a stronger and
12 more resilient grid through both the prevention of
13 faults and the mitigation of faults when they do
14 occur.

15 Our transformer and breaker upgrade
16 project. This is really about preventing the
17 impacts of future failures. We're targeting assets
18 that are at end of life and we are proactively
19 replacing those prior to failure, prior to the point
20 that they cause either a direct outage or a voltage
21 sag on the grid that can impact our sensitive
22 industrial customers or other problems.

23 And then finally capacity and customer
24 planning. This is about meeting customer and

1 capacity demands and obligations. Under the
2 transmission system we're obligated to meet our NERC
3 reliability standards. We're also obligated to meet
4 our new customer connections for
5 commercial/industrial customers and of course,
6 coordinating with our distribution department for
7 retail customer needs.

8 I'll introduce here a view of the -- the
9 portfolio view of the transmission projects. What
10 you can see on the left side is sort of the
11 investment view. This is the Duke Energy Progress
12 system level investment across the various project
13 areas. And I'll talk a little bit more to the
14 various improvement categories here on this slide.

15 I mentioned intelligent equipment upgrades
16 under our system intelligent project. This type --
17 this is installing digital relays that have much
18 more capability than the Legacy electromechanical
19 devices primarily made up of cams and levers.
20 Again, this is getting more information back to our
21 grid operators.

22 Hardening and resiliency is broken down
23 into several categories. Transmission line
24 hardening and resiliency. This is really upgrading

1 structures. You think about replacing wooden
2 structures with steel structures for our H frame.
3 We'll see some pictures of that. And also replacing
4 transmission towers that are at the end of life or
5 subject to failures due to certain degradation
6 mechanisms.

7 And when we upgrade these towers and
8 structures, we're rebuilding them to the latest
9 standards capable of withstanding more extreme
10 weather events. This project are is particularly
11 beneficial during those storm events and extreme
12 weather events.

13 Vegetation management, very similar to the
14 customer delivery project. The hazard tree
15 removals, we are targeting our outside of the
16 right-of-way. We identify threats. We remove the
17 trees that could result in threats and impact the
18 transmission system.

19 The transformer and breaker upgrade
20 project area, both of these projects are about
21 targeting assets that are at the end of life,
22 proactively replacing those assets. And at the same
23 time we're upgrading the capability of those assets.
24 So when we replace a circuit breaker or we replace a

1 transformer, we are installing in parallel to this
2 upgraded communication devices, protection and
3 control relays, again, to be able to better control
4 that equipment, restore that equipment following an
5 outage condition and get more information such as
6 system voltages and currents and power back to our
7 grid operators and our grid engineers responsible
8 for end-of-life planning.

9 Capacity of customer planning, this is our
10 largest category of work here. You can see on the
11 bottom of the stack, the VAR chart. This is
12 expanding capacity for customers as load is added to
13 the system, as resource population centers change
14 and move around the state. We have to plan that
15 into our substation and transmission circuit
16 projects.

17 We're also informing these projects
18 through our ISOP process that you heard of earlier.
19 So as we look at a capacity need, we are screening
20 that through our ISOP process to look, is there a
21 nontraditional solution or a non-wires alternative
22 to a traditional transformer upgrade or a circuit
23 rebuild. And that's allowing us really to look at
24 the best benefit-to-cost ratio for the given

1 solution and move forward with implementing it.

2 This category of work also includes our
3 transmission expansion projects. These are
4 sometimes referred to as the red zone expansion
5 projects. And what these projects are targeting is
6 looking at the areas of the Duke Energy Progress
7 system that have the maximum solar viability from
8 ability to connect solar generation resources and
9 we're overlaying those areas with areas of the grid
10 that are constrained and I use the term maxed out or
11 near maxed out. They are very limited to be able to
12 add additional renewable energy resources and we are
13 targeting upgrading those circuits and in some case
14 substation equipment to accommodate additional
15 renewable energy resources. For Duke Energy, this
16 is a very important part of our clean energy
17 transition to be able to deliver to our customers a
18 cleaner energy future.

19 The secondary benefit of these projects is
20 we're delivering reliability benefits. We're
21 replacing aged conductor. We're replacing wooden
22 structures with steel structures designed to the
23 latest standards. And we're hardening those systems
24 as we rebuild the circuits.

1 The last thing on this slide I'll mention
2 is the cost by the overall project as well as by the
3 project location is included in the transmission
4 details exhibit. And I will note that the project
5 location details and costs are as of early June
6 timeframe and these projects continue to be refined
7 as we move them through our development and
8 estimating process under our project management
9 process, particularly those projects in the outer
10 years of the three-year multi-year rate plan.

11 So as those advance in maturity between
12 June and when we ultimately file the rate case, we
13 will expect to see some changes in both in-service
14 states and costs associated with these projects.

15 I'd like to talk a little bit about how
16 we've built the transmission multi-year rate plan
17 portfolio and how we've selected the project
18 locations that are included.

19 What you see in the middle of this slide
20 are our two different organizations; our system
21 planning organization -- again, similar to Mr.
22 Guyton talking about distribution planning
23 engineers, transmission planning engineers are
24 looking at capacity needs for the system. They're

1 working very closely with our distribution planners
2 and our generation planners as well.

3 Our system planning engineers are also
4 responsible for our NERC compliance obligations
5 ensuring that we meet the obligations of the North
6 American Electric Reliability Council and that as we
7 model the transmission system and model certain
8 failure scenarios, we will not overload the system,
9 we will not result in catastrophic impacts,
10 cascading impacts, brown outs. So those planning
11 engineers are responsible for that part of the
12 portfolio.

13 The asset management engineers and subject
14 matter experts are really about end-of-life
15 planning. So I mentioned predicting where we're
16 going to have future failures and preventing those
17 failures. Technology upgrades to facilitate a
18 smarter grid that is more capable of providing us
19 information on where failures will occur, where
20 problems on the grid are occurring.

21 So we take various different inputs from
22 field inspections, from asset health trending,
23 technician and lineman input, industry and industry
24 data, and we take that information, we target the

1 specific location that needs work, and we initiate
2 and we score that project in a variety of areas.
3 And what you can see around the outside of the
4 circle here are the different areas that we're
5 looking at from a benefit to cost prospective.

6 We use a third-party software that is
7 specifically designed with various value models to
8 build a benefit. And in terms of each specific
9 project location, we score that project to -- in the
10 various value models to determine that benefit. So
11 we're looking at financial risks, security and
12 safety, compliance with our regulations,
13 environmental and property impacts, grid capacity
14 due to growth and changing demands. And then, of
15 course, reliability and integrity. Pause for a
16 moment.

17 Reliability is really the largest area
18 from a benefit perspective. Similar to the customer
19 delivery organization in the distribution grid we're
20 using the ICE calculator to determine the cost of an
21 avoided outage or essentially looking at what is --
22 if we can avoid this outage, how do we monetize that
23 cost and how do we use that as the benefit that
24 would be achieved through the product -- through the

1 project in that specific location.

2 And again, similar to Mr. Guyton, we are
3 using DEP specific information. That ICE calculator
4 is actually embedded in our third-party software
5 that we're using for this prioritization framework.
6 Again, we worked through the benefit to cost
7 analysis for those locations and the most beneficial
8 projects are optimized and ultimately built into our
9 multi-year rate plan.

10 The last thing I'll mention is we are
11 evaluating the specific different mix of customer
12 classes when we look at a benefit, so we're using
13 three different classes; residential, small C&I, and
14 then large commercial and industrial as well to
15 factor into our benefits.

16 I'm going to start diving into our
17 specific project areas and I will talk mainly about
18 the description of the project and then I'll get
19 into the benefits of these projects and we'll look
20 at one specific project location in each of the
21 seven areas and talk about what that looks like.

22 So what does system intelligence mean?
23 Quite simply as I mentioned earlier, it's our
24 ability to obtain more useful data about the grid

1 and about our assets, so that we can make smart
2 decisions in the best interest of the reliability of
3 our customers.

4 Digital relay. As you can see in the
5 bottom right picture, these blue boxes on the screen
6 are digital relays. They're small computers that
7 are installed in place of traditional
8 electromechanical devices.

9 What is a relay? It's simply a device
10 that senses a problem on the transmission grid,
11 generally a fault condition, and it sends a signal
12 to a circuit breaker to open the breaker and isolate
13 the fault. We're very interested in keeping faults
14 isolated the smallest possible section of the grid
15 and that minimizes the impacts on customers when we
16 can effectively do that.

17 These digital relays are not only more
18 reliable in sending those signals to circuit
19 breakers and very quickly in a matter of fractions
20 of a second isolating faults, but they also provide
21 supplemental information to our operators and to our
22 engineers.

23 The historical means of actually finding a
24 fault on a transmission line, you can think of a

1 long transmission line maybe 30 miles or more, when
2 we have a fault, we have no intelligent devices
3 telling us where that fault occurs, our energy
4 control center only knows that the breakers on each
5 end of this line opened. Somewhere in the middle of
6 this 30 miles we have a problem. We have to
7 dispatch linemen and start driving down
8 right-of-ways. In some cases it's very difficult to
9 access these right-of-ways. They're not generally
10 along roadways.

11 With intelligent devices, we have a better
12 idea and in some cases a very specific location down
13 to the structure number on where that fault
14 occurred. We can use technology and algorithms to
15 take that fault current that comes into our system,
16 plug that into an algorithm as I mentioned and
17 determine the distance to fault. We can then
18 dispatch the lineman directly to that location.
19 They can assess the problem. They can determine if
20 there's a switching solution, which I'll talk a
21 little bit more about in another project area, and
22 then -- or they can determine if there's a repair
23 that they can immediately make. Perhaps it's
24 cutting a tree off a line. Perhaps it's replacing

1 an insulator that was damaged by lightning. This is
2 the real benefit of our digital relay upgrade
3 project area.

4 Remote asset monitoring is the second item
5 I'll mention here, both remote asset monitoring and
6 substation monitoring. Most folks are familiar with
7 traditional SCADA which is getting information from
8 substations back to the control center, being able
9 to control that equipment.

10 When we talk about asset monitoring, that
11 takes SCADA down to the level of a specific asset.
12 In this case transformers. Transformers are a very
13 important asset on the transmission grid. They are
14 transforming voltage from various different levels
15 within transmission voltages and down to
16 distribution levels to distribute it out to
17 customers on the grid.

18 When these transformers can tell us hey, I
19 have a problem, I am sick, I need attention, that's
20 a huge benefit. I'll share an analogy here. I
21 recently received an email and taking a look at it,
22 it said your printer is low on ink. Very simple
23 technology said your printer is low on ink. You
24 have X amount of pages left to print before this

1 asset fails. That's the type of technology that
2 surprisingly many places of our transmission grid we
3 have not yet implemented because the technology is
4 relatively new.

5 This condition-based monitoring technology
6 where we can have an in-line gas meter analyzing
7 potential fault gases that are accumulating and are
8 critical power transformers sending that information
9 to our engineers and subject matter experts so they
10 can make these decisions on essentially how long do
11 I have before this transformer fails or before I
12 need to take it out of service to proactively
13 inspect it or do some additional maintenance. So
14 that's really our asset monitoring program.

15 Remote switches I'll talk about more on
16 our next slide here.

17 I'm going to go back to the example of
18 when a line locks out. So we have a fault on the
19 transmission system and two breakers at either end
20 open. The transmission system is constructed with
21 various line switches. These are large switches at
22 the 230-kV and 115-kV levels generally and these
23 switches do allow some operational flexibility to be
24 able to further segment faults and isolate those

1 faults down to smaller areas so then we can restore
2 customer retail stations. We heard discussion about
3 retail stations earlier which serve the majority of
4 our customers.

5 Traditionally these switches are manually
6 operated. So again, that lineman, once the fault is
7 identified, once the location is identified, they
8 will then have to drive to a switch which could be
9 multiple miles, tens of miles away from where
10 they're at. Open the switch using a crank handle.
11 Notify the control center that now they can restore
12 load using breakers at the substation. And the
13 control center can make that action.

14 We are deploying more remote operated
15 switches built in new locations and upgrading manual
16 switches with these remote operating switches. This
17 gives the capability for grid operators to be able
18 to make those switching manipulations remotely from
19 the control center. When we combine that technology
20 with digital relays that give the location of the
21 faults, we go from a matter of hours to resolve a
22 transmission outage to minutes.

23 So there is still some manual action from
24 the control center required, but it can be done in a

1 matter of minutes and I would call this program
2 somewhat akin to the self-optimizing grid program on
3 the distribution side. It's really a significant
4 way to mitigate the impacts of a fault or an outage
5 occurring on the transmission system.

6 This specific project location is the
7 Delco Whiteville remote control line switch
8 installation. This transmission circuit is in the
9 coastal plain area of North Carolina. It's
10 susceptible to flooding. It's in low-lying areas.
11 You can see kind of a swampy area in the bottom
12 right picture on this right-of-way. It's very
13 difficult to access. When we have a lightning
14 strike or a tree that comes down onto a line or some
15 other it could be a component failure itself, a
16 structure failure perhaps during a weather event or
17 a hurricane event, it's very difficult to access and
18 restore and make that repair. By having these
19 remote operated switches, we can really tighten up
20 the area of the faulted segment of line, restore
21 more customer load in a faster scenario.

22 So this specific project improves the
23 reliability for more than 11,000 customers directly
24 served off this transmission line. And that's from

1 four separate substations.

2 The line hardening and resiliency project
3 will be the next one I'll discuss. Several
4 different areas where we're targeting improvements
5 in this area.

6 First one is our cathodic protection
7 project. You'll see down in the bottom left a
8 picture of a failed transmission tower. This tower
9 actually came down during a hurricane event and
10 postmortem inspection revealed that the tower legs
11 were corroded. Many of our transmission towers are
12 direct embedded into the ground, which means their
13 support structure maybe embedded underground so
14 they're subject to groundwater and soil corrosion
15 environments.

16 When we install a cathodic protection
17 system, which is a series of protective anodes
18 actually attached to those tower legs, we are
19 protecting and arresting and mitigating the
20 corrosion on these metal towers and that greatly
21 improves the structural integrity of these towers
22 particularly again during extreme weather events
23 where we have high wind scenarios where we have
24 scenarios that are susceptible to cause damage to a

1 transmission tower.

2 The targeted line strengthening for
3 extreme weather scope, you can see a picture in the
4 middle here. This is a typical H frame design
5 transmission structure. This is very common in our
6 territory on the 230-kV and 115-kV systems. What we
7 are doing is replacing vulnerable and aged wood
8 poles and upgrading them with steel poles.

9 When we replace a wood pole with a steel
10 pole, we're designing that to the very latest
11 standards. We heard about the NESC standards
12 earlier. The -- in a coastal area for example a new
13 pole that's installed is designed up to 140 mile an
14 hour wind scenario, so that's a great improvement
15 over the traditional design that in the traditional
16 standards that were in effect when these poles were
17 installed 50, 60, 70 years ago. So again, we're
18 targeting specific poles that we have identified as
19 degraded. We're upgrading them to steel and in most
20 cases we've greatly reduced the chance of that pole
21 failing during a extreme weather event or other
22 scenario.

23 Transmission tower is very similar. We're
24 targeting specific types of transmission towers that

1 are susceptible to failure. In these cases the
2 degradation is not just at the ground level, but
3 it's up higher parts of the tower that we can't
4 arrest the corrosion or the degradation through a
5 cathodic protection, so we're targeting replacement.
6 I'll talk about a specific example of that on the
7 next slide.

8 The last one I'll mention is the animal
9 mitigation project scope. And this is a specific
10 project targeted at our 500-kV system. One thing
11 that occurs on the 500-kV system is buzzards love to
12 roost on 500-kV towers. You can see these as you're
13 driving under systems down highways in certain areas
14 past our largest transmission towers.

15 Buzzards result in contamination directly
16 underneath where they roost and that results in
17 flashover events and these flashover events are very
18 significant on the 500-kV system particularly
19 impacting our industrial customers. So when we have
20 sensitive manufacturing companies connected to our
21 transmission grid, the faults in the voltage sags
22 that happen on the 500 system, they transfer down
23 into the 230-kV, the 115-kV and even down in some
24 cases to the distribution level voltage. By

1 preventing those faults from occurring through
2 animal mitigation coverups, we are eliminating that,
3 the voltage sag, from that structure that the
4 project is implemented on.

5 You can see the benefits in the CBA
6 numbers here. I'm going to jump right into
7 discussing a little bit more about this specific
8 project location. This system, Mayo-Person 500-kV
9 targeted line strengthening project. And what you
10 see is the -- the picture on the left you see a
11 bolted joint. These transmission towers have many
12 hundreds of bolted joints. This specific line is
13 designed a material called weathering steel and it's
14 a steel material that has a corrosion patina on it.
15 It's brown in color and ideally what that does is
16 arrest and prevents any more severe corrosion from
17 occurring.

18 What has begun to happen on these towers,
19 though and this is a common issue in the industry
20 with this design of transmission tower, is these
21 joints, these bolted joints are actually expanding
22 due to corrosion and they're creating tensile
23 stresses on these bolted joint that will eventually
24 lead to bolt failure and weakening of the tower.

1 The 500-kV system is really the
2 superhighway right at the transmission system. You
3 heard Mr. Guyton talk about the transmission system
4 as really the highway system and if we think about
5 the 230 and 115 system as our state routes, our
6 500-kV system is really those interstates, right?
7 It's your I40s and I95s. It's very important to
8 move large amounts of power around the system.

9 Our customers are typically not directly
10 connected to this system, but it's very critical
11 particularly in peak winter and summer seasons.

12 This particular line supports about 500 MW
13 of network flow, which is enough power for 300,000
14 homes, so very significant amount of power flow
15 through these lines and it is our mission to prevent
16 the failure and the resultant emergent tower
17 replacement costs and potential power flow impacts
18 that could happen to our transmission grid if this
19 was to occur depending on the type of year where
20 this would occur.

21 The last thing I'll mention on this Mayo
22 Person Project is the solution to address the
23 corrosion concern with this type of tower. We
24 looked at multiple different solutions, multiple

1 different types of repairs and replacement options
2 and replacing the tower with a non-susceptible
3 material that is not subject to this corrosion
4 phenomenon. It is selected as the best solution
5 from a benefit to cost standpoint and ultimately the
6 standpoint to be able to reliably serve our
7 customers in all of our weather conditions.

8 Next slide is the substation hardening and
9 resiliency project. Several different project areas
10 I'll go through here. Substation rebuilds is the
11 first one.

12 Substation rebuilds are all about
13 replacing degraded wooden structures within our
14 substations. Many of our substations that transmit
15 power from the 230 or 115-kV system down to
16 distribution level voltage is 24-kV, 13-kV in some
17 places. Those are using wooden horizontal and
18 vertical members.

19 So similar to the wooden transmission
20 tower program, our substation rebuilt program is
21 eliminating these wood structures. You can think
22 about these wood structures as really the skeletal
23 system of the substation. They are supporting and
24 holding up the vital organs, right? The

1 transformers, the breakers, the instrumentation
2 that's really critical for delivering the power to
3 our customers.

4 When the skeletal system starts to fail,
5 the supported assets start to fail and what we're
6 seeing is that these wooden structures are
7 splintering, they're warping, they're causing
8 equipment to come out of alignment and we're
9 replacing those with steel structures. And at the
10 same time we're upgrading our targeted breakers and
11 transformers and system intelligence scope work that
12 overlaps where there are other project areas.

13 The substation flood mitigation scope
14 pretty straightforward. We are mitigating the
15 impacts of floods. We are either relocating
16 substations out of flood-prone areas or elevating
17 equipment or in substation -- in some locations
18 building a flood wall.

19 Animal mitigation. The animal mitigation
20 scope is really installing animal mitigation fences
21 around our substations. Animals are a very
22 significant contributor to transmission outages.
23 When an animal contacts equipment inside a
24 transmission station, the design of the equipment is

1 typically to lockout. So the breaker opens, right?
2 This prevents more significant damage to equipment
3 and collateral damage, so when animals contact lines
4 or circuits, that's not always the case. Mr. Guyton
5 talked about momentary impacts in -- when animals
6 impact substations, it's a sustained outage that
7 often impacts customers.

8 By putting in specialty fences, we're
9 preventing snakes and squirrels and raccoons from
10 getting into our stations greatly reducing the
11 chance of an animal causing an outage.

12 Physical security. Very similar except
13 instead of animals, we're keeping people out of
14 substations. So whether it is intentional or
15 non-intentional, our most critical substations we're
16 installing high-security fences. We're installing
17 intrusion detection equipment and other related
18 equipment to make sure that we know the status of
19 and again, keeping people out from causing
20 intentional or unintentional damage or harm to
21 critical transmission substations.

22 Specific example I'll mention for
23 substation hardening and resiliency is our Raeford
24 South 115-kV substation rebuild. You can see an

1 example on the lower right of what these wooden
2 structures look like that support equipment. And on
3 the left is the transformer at Raeford South that
4 we're targeting the upgrade on. And again, I'll
5 talk more about transformer upgrades and the drivers
6 there in just a moment.

7 But this is rebuilding this substation,
8 replacing the equipment that is in need -- that is
9 at end of life and is at risk of failure to prevent
10 those future impacts to our customers. And again,
11 eliminating those wooden structures upgrading
12 everything to steel structures designed to the
13 latest standards.

14 This is a smaller station. It serves
15 approximately a thousand retail customers. Still an
16 important station for our retail customers in the
17 Raeford, North Carolina area.

18 Vegetation management. Our vegetation
19 management project area is very similar to the
20 distribution project you heard of earlier. We're
21 really targeting hazard tree removals outside of our
22 right-of-way.

23 What you can see in the image on the left
24 tier is a scan that was taken from an aerial patrol.

1 All transmission circuits are patrolled using aerial
2 flights on a periodic basis. We're actually
3 scanning our transmission circuits and we're
4 building a hazard tree risk model to specifically
5 target area or identify areas that we have risk with
6 a tree -- with a potential tree falling.

7 So the red polygon areas you can see in
8 the picture here, these are actually called threat
9 areas. And this is our tree canopy risk model.
10 Once we have our threat areas built from the
11 scanning, we have our subject matter experts review
12 the right-of-ways and determine if further action is
13 needed. In most cases, the -- if further action is
14 needed, we go remove the tree. The tree may be
15 particularly tall or particularly wide, and the
16 scanning technology actually determines if this tree
17 falls based on the location of the center line of
18 the conductor and where the tree is, if it will
19 impact the transmission line or not. So we're
20 specifically targeting these trees that will impact
21 a transmission line upon failure and upon falling
22 into the right-of-way from outside the right-of-way.

23 The work executed, again, under this
24 project is really looking at not just trees that

1 are -- that are unhealthy or that are already
2 leaning, but it is looking at any tree that could
3 potentially cause a problem on that transmission
4 circuit.

5 A specific location that I'll mention here
6 for this project areas are Harris Plant to Siler
7 City 230-kV. Before I get into that, I will mention
8 another similarity to Mr. Guyton's discussion. The
9 hazard tree removal or vegetation management project
10 does not have a quantitative cost-benefit analysis.
11 It's a qualitative analysis. And for the same
12 reasoning we see this as an obligation to serve our
13 customers. We are -- this is a necessary program
14 area that we've executed for some time.

15 The Harris Plant Siler City 230-kV line
16 south of Raleigh here. This is a 33-mile line
17 connecting the Harris Nuclear Plant approximately
18 1,000 MW generating station to three different
19 substations, four different transformer banks. This
20 serves approximately 20,000 customers. This is a
21 100-foot right-of-way.

22 Our scanning which is using a lidar
23 technology. It's a type of scan. We are
24 identifying threats up to 30 feet outside of that

1 right-of-way. And then we're proactively targeting
2 removal of those trees that have been deemed to be
3 threats and falling risks for that transmission
4 line.

5 For transmission-specific outages, about
6 25 percent of customer minutes interrupted are from
7 trees from outside the right-of-way. So one-quarter
8 of all customer outages that emanate from the
9 transmission system are coming from trees outside of
10 the right-of-way, so it's a very significant project
11 for us for customer reliability.

12 I'll move next into our circuit breaker
13 upgrade project. This upgrade project is targeting
14 assets that are at the end of life. Particularly,
15 we're targeting oil circuit breakers. Oil-filled
16 circuit breakers are a legacy technology. It is an
17 oil-filled tank. That oil actually arrests the
18 fault and the arc gases, and it extinguishes the arc
19 when a circuit breaker opens or closes.

20 It's an outdated technology and these
21 breakers are prone to failure. Our strategy here is
22 identify assets that are beyond the end of useful
23 life that have a expectation for failure based on
24 make, model, trending, that we have based on the

1 number of operations and the number of faults.
2 That's data we gather. Essentially, the more a
3 breaker operates the more wear it is getting.

4 We also are targeting locations based on
5 the number of customers served, the configuration.
6 Is it networked? In other words, is there
7 redundancy or is it a radial system? There is no
8 redundancy built in.

9 So we're taking all these inputs, we're
10 targeting the locations, and then we're replacing
11 that oil circuit breaker with an upgraded
12 technology. We're using vacuum circuit breakers.
13 It's a vacuum chamber that extinguishes or prevents
14 an arc from occurring for distribution level
15 voltages, so that would be transmission -- the
16 assets in a transmission substation less than 44-kV.
17 And then for the higher voltage assets we're using
18 pressurized gas breakers, which is the
19 state-of-the-art modern standard for fault
20 interruption at the transmission level.

21 And again, as we upgrade those assets,
22 we're installing upgraded protection and control
23 relays, digital relays that can get us that
24 additional information for remote monitoring and

1 control of the grid.

2 One important factor with circuit breakers
3 is, and I alluded to this earlier, if a circuit
4 breaker does not operate reliably, that is to
5 isolate a fault, the section of the transmission
6 grid that isolates grows, right, the backup breakers
7 need to operate. So this could be at remote
8 substations further out on transmission lines at
9 adjacent transmission stations and, therefore, more
10 customers are interrupted. So getting a circuit
11 breaker -- ensuring a circuit breaker reliably
12 operates the fault when given a signal to open is
13 very important to minimize the impacts on our
14 customers.

15 Every time a circuit breaker fails and --
16 when a -- I'll say too then. When a fault occurs
17 and particularly when a circuit breaker fails to
18 open, in addition to that, that direct failure for
19 the customer served on that line, we're also getting
20 a voltage sag on the system. So this is the same
21 for a transformer failure as well. These failures
22 do result in significant voltage sags that impact
23 our sensitive industrial customers and manufacturing
24 customers, so it's our goal to prevent those impacts

1 and proactively address these assets.

2 This specific project location, the
3 Milburnie 230-kV substation supports the greater
4 Raleigh area. This is east of Raleigh. And we are
5 targeting the replacement of five 115-kV circuit
6 breakers. You can see a picture on the lower right
7 of what these oil circuit breakers look like.

8 This specific station I mentioned is very
9 critical, so five different lines come into this
10 station. Those lines go out to serve 77,000
11 customers. In this specific station, we actually
12 had a recent outage event where one of the breakers
13 did fail to operate in the required clearing time
14 and breakers further out opened. We directly
15 impacted 17,000 customers on that one outage event,
16 so a single fault on the transmission system and
17 17,000 customers impacted. So that type of event is
18 exactly what we're looking to avoid and eliminate
19 will greatly reduce the impacts of during while
20 executing this project.

21 Transformer upgrades, again, some
22 parallels to breakers. I mentioned earlier our
23 transformers transform voltage from transmission
24 levels to other transmission levels, so 500-kV to

1 230, 230 to 115. That's for connecting out to the
2 various levels of the transmission system for bulk
3 power flow. And then they also transmit or
4 transform voltage from the 230-kV to 115-kV system
5 down to the 24-kV system commonly in the DEP area.
6 So these are critical assets for serving our
7 customers.

8 What we're doing is, again, we're
9 targeting specific transformers that are at end of
10 life. We're using field inspections, visual
11 inspections, electrical testing. We're using make,
12 model information, trending information, vendor, and
13 industry data to select what assets are prioritized
14 for replacement. We're scoring those projects,
15 again, using the model that I talked about earlier
16 on based on that specific location, the number of
17 customers served, the voltage level, et cetera.

18 This project also includes regulators.
19 Regulators are -- substation regulators specifically
20 are very similar to transformers. One moment.
21 Whereas transformers transform voltage over large
22 areas, regulators control voltage over a very tight
23 band, so plus or minus one volt in some cases. And
24 we are obligated to maintain this voltage out on our

1 systems. And you heard a little bit about voltage
2 regulation earlier from Mr. Guyton. A regulator in
3 a transmission substation controls the voltage for
4 all the circuits leaving that station. And we'll
5 look at an example of that on the next slide.

6 One of the keys things this project
7 eliminates is a vulnerable arc-in-oil design for
8 load tap changers. As we see more and more
9 renewable energy resources and particularly variable
10 energy resources connect to the grid, this
11 arc-in-oil technology is a specific vulnerability.

12 But essentially it's an oil tank where,
13 again, similar to a breaker, as a voltage regulator
14 or a transformer controls voltage, there's an oil
15 tank where this arcing occurs. Gases can accumulate
16 in that oil tank over time and lead to catastrophic
17 failure.

18 When a transformer or a regulator fails
19 catastrophically, there's often release of oil.
20 There is often collateral damage due to the size of
21 this equipment and the amount of energy that's
22 stored in there and the amount of oil that's stored
23 in there. So in addition to just that asset
24 replacement cost, the collateral damage and the

1 impacts of the equipment adjacent to it in a
2 substation can be very significant from a cost
3 standpoint and also from a time standpoint for
4 recovering from that outage event.

5 So again, these are reasons why we want to
6 proactively address these assets that are at end of
7 life, replace them prior to failure, prior to the
8 customer being impacted, and prior to the grid being
9 impacted by that failure.

10 New designs use a vacuum load tap changer
11 that eliminates this vulnerable technology, again,
12 particularly susceptible to when we have variable
13 energy resources and we have a lot of voltage
14 regulations as we see cloud-cover changes.

15 The specific example or project location
16 I'll speak to for our transformer upgrade project is
17 the Wilmington-Ogden 230-kV three-phase regulator
18 replacement. This is in the Wilmington, North
19 Carolina area. We are replacing a three-phase
20 stations regulator. This one regulator provides
21 voltage control for four different distribution
22 circuits leaving that station. Those circuits serve
23 over 8,500 customers.

24 The last thing I'll mention here is

1 three-phase regulators are the top outage cause
2 category for substation equipment failures in DEP
3 for, again, outages emanating from the transmission
4 system. When we look at substation equipment, we've
5 had over 11 million customer minutes interrupted in
6 the last five years. So it's very important for us
7 to target these assets, upgrade these assets with
8 non or with designs that are less vulnerable to
9 these failures.

10 Going to move onto the last project area,
11 which is our capacity and customer planning project
12 area.

13 This type of work is very critical to meet
14 the capacity needs of our customers. I mentioned
15 earlier our interrelationships in working between
16 our customer delivery planners, our generation
17 planners, and our transmission planners making sure
18 we can project the needs for growing and shifting
19 customer demands in our territory.

20 In addition to this, we have an obligation
21 to meet our NERC compliance requirements and this
22 includes modeling the transmission system under
23 certain failure scenarios. Because the transmission
24 system can impact so many customers upon a single

1 failure, we have compliance obligations to plan for
2 a single failure scenario and plan for different
3 scenarios that may impact the grid. So if we lose
4 certain equipment, what's the result and impact?
5 Will it result in overloads? Will it result in
6 cascading outages? You know, impacts that go much
7 beyond one substation to larger areas of the grid.

8 So this area, this project area is all
9 about mitigating those impacts and planning for
10 those future potential consequences to the grid.

11 I mentioned earlier these capacity
12 projects are informed through the ISOP process, so
13 we are screening capacity upgrades for non-wires
14 alternatives such as battery storage and we are
15 moving forward with the best option from a
16 cost-benefit perspective approach.

17 I'll talk again about our transmission
18 expansion plan, aka our red zone projects and go
19 into a little bit more detail here.

20 We have 11 projects that are targeting
21 capacity upgrades in our territory. Again, these
22 red zones are areas where we have maximum solar
23 viability and we have minimum capacity. We feel
24 it's truly important to transform the grid to this

1 -- to the clean-energy future and upgrading these
2 lines is really a key part of that transformation
3 for us.

4 The many interconnection studies over many
5 years have identified the need to upgrade these
6 circuits and have proven the need.

7 We are also processing these projects
8 through the North Carolina Transmission Planning
9 Committee and the Transmission Advisory Group
10 specifically to obtain shareholder input.

11 The Transmission Planning Committee
12 Oversight Steering Committee will ultimately have to
13 approve these projects and this is all in line with
14 FERC requirements for transmission additions.

15 These projects are an important part and
16 not just from the energy perspective, but also
17 important part of our plan from reliability
18 perspective. We're delivering significant
19 reliability benefits and we're also evaluating these
20 projects under a traditional benefit-to-cost
21 reliability model, as we do our other projects. We
22 are looking at the conductor replacement, the
23 structure replacement, and the mitigating impacts
24 of, you know, preventing failures due to upgrading

1 that equipment.

2 We do understand additional discussion on
3 these projects is ongoing with carbon plan
4 proceedings.

5 One specific project location I'd like to
6 discuss is the Craggy Anka Capacity Project. And
7 this project, you can see on the picture on the
8 right side the north and south parts of it, is the
9 general Asheville area. You can see the yellow
10 line, that's an existing 230-kV transmission
11 circuit.

12 Conspicuously in the middle, there is no
13 230-kV circuit between the Craggy and the Anka
14 substation, so we're missing this corridor kind of
15 in the central Asheville area here or to the west
16 side where we are limited at how much power we can
17 transmit between the different parts of the system.

18 And our planning models have actually
19 identified a potential load shed outage scenario by
20 the winter of 2025 based on limited ability to move
21 bulk amounts of power between the system. So we're
22 building a 230 volt connector line between these two
23 points. And we're doing that in a least impact way
24 as possible. We're using an existing 115-kV

1 right-of-way that spans between these two stations.
2 You can see an artist rendering in the lower
3 left-hand side of the picture where we're actually
4 going to be putting the existing 115-kV circuit
5 rebuild on one side of the structures and the new
6 230-kV line on the other side of the structures.

7 So I mentioned the benefit. Directly this
8 project serves approximately 30,000 existing
9 customers from this line and in the greater
10 Asheville area, much larger number of customers for
11 general voltage stability and grid stability in the
12 greater area.

13 Okay. And the last slide will be our
14 closing remarks. Justin?

15 MR. BROWN: If you want to click the last
16 slide. I just want to say, you know, we've
17 certainly provided a lot of information today and in
18 our prefiling materials that we did. We believe the
19 projects today for both transmission and
20 distribution compliment each other in supporting the
21 clean energy transition in North Carolina really to
22 build a grid that has -- can accommodate two-way
23 power flow that has increased automation, overall
24 situational awareness for the grid, and really

1 postures us overall for increased reliability and
2 resiliency overall for the system. Certainly
3 postures us for a safe expansion of renewable
4 generation and distributed energy resources at the
5 edge of the grid along with providing equitable
6 benefits for customers across the entire system done
7 in an affordable way.

8 Thank you for your time today.

9 CHAIR MITCHELL: All right. Thank you
10 all. Let me check and see if there are questions
11 from the Commissioners. Commissioner Clodfelter?

12 COMMISSIONER CLODFELTER: This is a
13 general question that speaks to both components, if
14 you're able to do so and, secondly, if you're
15 willing to do so, and I understand both conditions
16 have to be met, can you forecast whether any
17 portions of these proposed projects will be
18 associated with a performance incentive metric in
19 the upcoming rate case? Are they going to be tied
20 to a performance metric?

21 MR. BROWN: So I do believe that
22 performance incentive metrics are a required
23 component of an MYRP filing.

24 COMMISSIONER CLODFELTER: They are, but

1 you only have to propose one out of a basket of
2 several you could propose, and I'm just trying to
3 find out whether this one might be one of the ones
4 you're going to propose.

5 MR. BROWN: When you say "this one"?

6 COMMISSIONER CLODFELTER: Associated with
7 your distribution and transmission projects. Are
8 you going to propose any performance incentive
9 metrics to measure your success or failure?

10 MR. BROWN: I do know that there will be
11 at least one, but I don't know if they are
12 specifically tied to these projects.

13 COMMISSIONER CLODFELTER: Don't know if
14 it's going to be associated with these projects.
15 That's all right. As I say, you might not know, but
16 even if you know you might not be willing to say
17 today, but I thought I'd ask the question to see.
18 All right. Thank you.

19 CHAIR MITCHELL: All right. Additional
20 questions for DEP? I see Commissioner Duffley.
21 Your hand is up.

22 COMMISSIONER DUFFLEY: Yes, thank you. So
23 going to slide 40, you were talking about new
24 delivery points for customers. And so my question

1 is which type of customers? Are you speaking of
2 retail customers or wholesale customers? And then
3 if you're speaking of retail customers, are you
4 speaking of residential, commercial, or industrial?

5 MR. BROWN: Sure. Thank you for the
6 question. Generally, industrial customers would be
7 the new customers that the transmission portfolio
8 would sponsor projects for. That would be new
9 industrial customers directly connected in the
10 transmission system. The retail projects would
11 typically come through sponsorship of the customer
12 delivery distribution arm.

13 COMMISSIONER DUFFLEY: Okay. Thank you
14 for that clarification. And then on page 42, you
15 were discussing the reduction of faults. I just
16 would like a sense of how many faults the
17 transmission system sees per year.

18 MR. BROWN: Sure. You know, it can vary
19 widely, particularly during storm scenarios. If we
20 look at sustained faults, sustained number of
21 outages, year to year it can vary from 50 to 100
22 outages. That's not uncommon. The average over the
23 past five years is approximately in the 70 range for
24 sustained faults. Momentary is significantly higher

1 than that. The transmission system is built with
2 reclosing capability on the circuits, so many
3 hundreds of faults obviously occurring on the
4 transmission system when you look at momentaries on
5 an annual basis.

6 COMMISSIONER DUFFLEY: Okay. Thank you
7 for that. I don't have any further questions.

8 CHAIR MITCHELL: All right. Just I would
9 like to follow up on the response there. So a
10 momentary fault, does that result in a disruption of
11 service to customers or is it -- can you help me
12 understand what that means in practical terms?

13 MR. BROWN: Yes. Good clarifying
14 question. A momentary fault is a fault that
15 interrupts customers that lasts for on the
16 transmission system one minute or less. So a fault
17 that occurs for 59 seconds would be a momentary.
18 One minute or more would be a sustained outage. So
19 it's certainly an impact that customers would
20 notice, particularly for those commercial and
21 industrial customers can be consequential, even at
22 the momentary level.

23 CHAIR MITCHELL: Okay. Thank you. All
24 right. Commissioner Clodfelter?

1 COMMISSIONER CLODFELTER: I'm going to be
2 asking a question. You may not have it there in
3 front of you but the question really comes from
4 Exhibit TC-9C. And I really just want to understand
5 what that exhibit is telling me.

6 So these are the capacity and customer
7 planning projects. And there's a table showing the
8 costs, the operational benefits, the customer
9 benefits, and the combined cost and benefits and I
10 follow the chart through the cumulative net benefit
11 turns positive starting in 2035 and in later years
12 out, so it's a upfront investment that you recover
13 over an extended period of time.

14 What I really want to understand is the
15 line under customer benefits that's titled
16 "residential/commercial/et cetera customers". So, I
17 mean, you've got a line above that which is the
18 customer outage benefits, so I assume that that
19 second line, residential/commercial/kcustomers
20 really doesn't include a lot of outage benefits or
21 traditional reliability benefits. It's including
22 something else there. And what is that? Is that
23 load growth? If it's not load growth, a lot of
24 these projects as you've already said are red-zone

1 projects that are increase system capacity to absorb
2 additional renewables. And so how does that
3 translate into the number that's shown on that line
4 of customer benefits? Is that -- are those societal
5 benefits?

6 MR. BROWN: So I am looking at that
7 exhibit and what I'm seeing here is actually the
8 avoided customer sustained outage benefits
9 residential/commercial/et cetera customers is all
10 one row. And then the total --

11 COMMISSIONER CLODFELTER: Oh, it's not two
12 rows?

13 MR. BROWN: No.

14 COMMISSIONER CLODFELTER: That's not two
15 rows. It's a single row.

16 MR. BROWN: That is correct. That is
17 correct.

18 COMMISSIONER CLODFELTER: Caught me. You
19 caught me on that. So that number then does include
20 the value of outage -- outages avoided and the cost
21 of outages avoided.

22 MR. BROWN: Yes, sir. That's correct.
23 That is using the ICE model. The societal benefits
24 in terms of avoided outage, in terms of avoided

1 outage cost.

2 COMMISSIONER CLODFELTER: Sure. But in
3 terms of, for example, the projects that are on the
4 list on page 5 there, a lot of which are the
5 red-zone projects, I've begun to recognize them by
6 now individual projects, to the extent those are
7 enabling retirement of carbon resources and
8 substitution of renewable resources. Are those --
9 is that substitution being valued in your
10 cost-benefit analysis? And if so, how is it being
11 valued?

12 MR. BROWN: At this point, those benefits
13 are not being valued quantitatively.

14 COMMISSIONER CLODFELTER: So then on this
15 TC-9C, that line that we just looked at which you've
16 now explained to me is a single line not two lines,
17 does not include the benefits from the enabled
18 conversion from fossil to carbon-free resources?

19 MR. BROWN: That is correct. Yeah. Of
20 course there is --

21 COMMISSIONER CLODFELTER: Thank you, sir.

22 MR. BROWN: -- difficulty in quantifying
23 that. We are -- it's certainly something that we
24 are interested in in the future.

1 COMMISSIONER CLODFELTER: We're all
2 interested in it. I just wanted to figure out if
3 you had found a way to quantify it and put it on
4 this page. That's what I was trying to find out.
5 Thank you.

6 MR. BROWN: You're welcome.

7 CHAIR MITCHELL: While you're looking at
8 TC-9C, page 5 of 5 of that exhibit, can you just
9 point me to the 11 projects that are in the red
10 zone? And I'm wondering if they're located on that
11 page 5 of 5. And if not, where would I find them?

12 MR. BROWN: Sure. You can -- they are
13 listed -- let's get to that page. We don't have
14 them uniquely called out as a sub -- as
15 subprojects --

16 CHAIR MITCHELL: Right.

17 MR. BROWN: -- within here. Now, they are
18 also listed -- I'm going to go to a different
19 exhibit because I have them more easily marked up,
20 and the Technical Conference MYRP Project Details
21 and Transmission Exhibit -- I don't have the number
22 right here -- but they are listed in there. I can
23 go through the titles of the locations if you'd like
24 them or we can provide that in follow-up.

1 CHAIR MITCHELL: Just provide it in follow
2 up; that would be helpful.

3 MR. BROWN: Okay. Thank you.

4 CHAIR MITCHELL: And just to make sure,
5 because I think I missed that, the exhibit you were
6 just referencing, is it TC-7?

7 MR. BROWN: Yeah. Make sure I -- yes,
8 that's correct.

9 CHAIR MITCHELL: Okay. All right.

10 MR. BROWN: TC-7, yes.

11 CHAIR MITCHELL: Okay. Thank you. While
12 I have the mic, I'm going to ask you one more
13 question about the ICE calculator. I've heard you
14 reference it now several times and we talked about
15 it during the discussion on the distribution
16 programs. And you mentioned that you-all have a
17 third-party model that you-all are using that
18 incorporates the ICE calculator.

19 So is the ICE calculator model being used
20 the same way for the transmission side as it is for
21 the distribution side? Okay.

22 MR. BROWN: It is very similar. I will
23 say we are using DEP-specific information fed into
24 that SAVe and SAFe variables and retail customer

1 class mix, or residential small C&I, large C&I, is
2 not exactly the same, so we are -- we have that
3 calculator and table embedded in the software. The
4 software then does that calculation. But from my
5 knowledge and working discussions with my peers,
6 customer delivery is utilizing the tables very
7 similarly.

8 CHAIR MITCHELL: Okay. I recognize that
9 benefits associated with investments in the
10 distribution system and benefits associated with
11 investments in the transmission system may be
12 different, but to the extent you're looking at a
13 same or similar benefit, are they being calculated
14 in the same way?

15 MR. BROWN: Think about that. Yeah. So
16 for an avoided outage we would calculate the benefit
17 the same way.

18 CHAIR MITCHELL: Okay. That's -- thank
19 you. That's helpful to me. That's a good example.
20 Okay.

21 Let's see, let me see if Commissioner
22 Brown-Bland has a question.

23 COMMISSIONER BROWN-BLAND: Yes, I do have
24 a question. With regard to your discussion about

1 the right-of-way, working the right-of-way, and you
2 gave an example where you're clearing 30 feet
3 outside of the right-of-way, is that work -- is that
4 to comply with any standard like a NERC standard or
5 does it exceed any required standard?

6 MR. BROWN: Yes. Thank you for the
7 question. We do have NERC compliance obligations to
8 implement a vegetation management program
9 specifically for our 230-kV system, 200-kV and
10 above. It does not specifically dictate distance
11 outside of right-of-way, but we are obligated to
12 have a program and to demonstrate how we are
13 preventing trees from encroaching upon our minimum
14 vegetation clearance distance. So we are going
15 above and beyond those minimum compliance
16 requirements from a reliability perspective.

17 COMMISSIONER BROWN-BLAND: Based on the
18 work that you've done so far, you know, in examining
19 all of that, is 30 foot kind of expected to be the
20 Company standard or would we expect to see this
21 change over time? Like would it expand to 35 or 40
22 feet out?

23 MR. BROWN: I am not a vegetation
24 management expert, so I couldn't weigh in on that.

1 I'm not sure the answer there.

2 COMMISSIONER BROWN-BLAND: Okay. Thank
3 you.

4 CHAIR MITCHELL: Okay. We're at five
5 o'clock and I'm going to check in with the court
6 reporter to see how she is doing and if she can
7 continue on.

8 COURT REPORTER: [Nods in agreement]

9 Okay. So since we are close to the end of
10 the presentation from Duke, I'd like to continue.
11 It's my understanding we have one interested party
12 that intends to present. Counsel, I'm looking at
13 you to confirm that.

14 MS. CRESS: Yes, Chair Mitchell.

15 CHAIR MITCHELL: Okay.

16 MS. CRESS: CIGFUR has a presentation.

17 CHAIR MITCHELL: Okay. So we will push on
18 then and finish up today unless someone raises a
19 strenuous objection.

20 (No response)

21 Okay. All right. Well, let's continue on
22 with questions from Commissioners. Commissioner
23 Hughes, do you have any questions? And then we'll
24 hear from McKissick and then Kemerait.

1 COMMISSIONER DUFFLEY: Commissioner
2 Hughes, you're on mute.

3 CHAIR MITCHELL: All right. Commissioner
4 Hughes, we cannot hear you. All right. Let's hear
5 from --

6 COMMISSIONER HUGHES: Is that better?

7 CHAIR MITCHELL: We can hear you now. Go
8 ahead.

9 COMMISSIONER HUGHES: The three objectives
10 that you laid out at the beginning of and then again
11 at the end were resiliency, expanded renewables, and
12 DERs, and you have this equitable assets to
13 benefits. We spent a lot of the day talking -- it
14 seems to me talking about the first two, a lot of
15 the modeling that went in, a lot of the technical
16 details. Could you just talk briefly about what
17 process you did for that third objective and was
18 there any quantitative modeling for that third
19 objective and kind of making tradeoffs and things?

20 MR. BROWN: Thank you. There's -- I would
21 say that the equitable access to benefits is not
22 really in a quantifiable way. Part of what we're
23 doing when we looked across the distribution and
24 transmission system is making sure that we didn't

1 concentrate necessarily investments or types of
2 investments in one particular area. They're
3 intended to be broad across the DEP service
4 territory, so that when new technologies do become
5 available, that all customers on the system can take
6 advantage of those.

7 And specifically too as Brent and Dan
8 mentioned, by grouping the projects together in a
9 localized area, we believe we're trying to ring the
10 value of the resources that we have on the system,
11 typically labor resources as well as materials, ring
12 the biggest value out of those implementations so
13 that we can have a eye on affordability overall for
14 the customer.

15 COMMISSIONER HUGHES: And so it's mainly
16 affordability?

17 MR. BROWN: Affordability and making sure
18 that the investments aren't necessarily concentrated
19 in one particular area of the system.

20 COMMISSIONER HUGHES: Okay.

21 MR. BROWN: Their broad nature.

22 COMMISSIONER HUGHES: Thank you.

23 MR. BROWN: You're welcome.

24 CHAIR MITCHELL: All right. Commissioner

1 McKissick?

2 COMMISSIONER McKISSICK: In the interest
3 of time, this is a pretty quick question. It kind
4 of follows up on one that Chair Mitchell asked
5 about, the 11 projects in the red zone. First, how
6 do you determine which of those to proceed with in
7 this particular proposal that's before -- that will
8 be, you know, submitted to us soon?

9 And then secondly, as I recall and my
10 recollections may be mistaken, there were I think 13
11 projects in the DEP territory in the red zone. Was
12 there consideration given to just knocking them all
13 out considering the need to meet that capacity, you
14 know, as expeditiously as possible?

15 MR. BROWN: Yes. I'll say the number of
16 projects has shifted and shaped some as we continue
17 to sort of most effectively bundle and combine. One
18 project also moved to now it's a need under our
19 transmission additions plan based on capacity
20 changes. So it's moving -- it's a little bit fluid
21 and that may be the difference between the 13, the
22 11.

23 These really are the bulk of projects as
24 we see as the priorities now to upgrade. So there

1 may be additional expansion-led projects in the
2 future, but these are the projects that we see over
3 the next three years in the time period of the
4 multi-year rate plan, critical projects to implement
5 the capacity upgrades on.

6 COMMISSIONER McKISSICK: Thank you. I
7 guess the thing I would ask as you continue to work
8 on this proposal is perhaps evaluating all of them,
9 you know, and moving forward with all of them if it
10 can logically be sequentially performed and executed
11 in a way that's, you know, cost effective that makes
12 sense, because there's a real need to address these
13 red-zone areas as expeditiously as possible.

14 MR. BROWN: Thank you.

15 COMMISSIONER McKISSICK: Thank you.

16 COMMISSIONER KEMERAIT: To follow up on a
17 couple of questions from Chair Mitchell and
18 Commissioner Clodfelter about the red-zone upgrades,
19 on page 55, the benefit-cost ratio for the red-zone
20 upgrades and the additional part of the program is
21 1.6, which I think is the lowest ratio of any of the
22 programs. Can you just briefly explain why this is
23 included in your program since it has the lowest
24 ratio of what you're proposing?

1 MR. BROWN: Sure. I'll expand on the
2 benefit-to-cost ratio for our capacitor customer
3 planning.

4 I recall this project area actually
5 includes the red zone for transmission expansion
6 projects, also includes the compliance of obligated
7 compliance projects for reliability, NERC
8 reliability planning and new customer connections
9 specifically industrial customers connecting to the
10 transmission system.

11 Compliance obligations, we do not actually
12 score through a benefit-to-cost process. Because
13 they are requirements under federal standards and
14 rules, we do include the cost of those projects. We
15 do not include the benefits. We skip the scoring.
16 And they are, you know, obligations to implement.

17 So that does drive the benefit-to-cost
18 ratio overall for this bundle of the project area
19 lower than some of the other areas.

20 COMMISSIONER KEMERAIT: Thank you.

21 MR. BROWN: You're welcome.

22 CHAIR MITCHELL: Just following up there
23 to make sure I'm clear. When you say compliance,
24 you mean compliance with --

1 MR. BROWN: NERC standards.

2 CHAIR MITCHELL: -- with NERC standards?
3 Okay. Okay.

4 COMMISSIONER KEMERAIT: And do you have
5 the ratio for just the benefit/cost ratio for the
6 red-zone upgrades themselves? Has that been
7 differentiated or separated?

8 MR. BROWN: We have not to this point
9 differentiated that.

10 COMMISSIONER KEMERAIT: Thank you.

11 MR. BROWN: You're welcome.

12 CHAIR MITCHELL: Go ahead.

13 COMMISSIONER CLODFELTER: The biggest bang
14 for the buck that you've got on the list here is the
15 Rockingham station uprate for the 500-kV uprate.
16 What's involved in an uprate? How do -- I mean, for
17 less than a million dollars you get a \$108 million
18 worth of a benefit; you get almost 15 percent of
19 your total benefit for less than a million dollars.
20 What's involved in a station uprate?

21 MR. BROWN: And that -- can you restate
22 the project please?

23 COMMISSIONER CLODFELTER: It's the
24 Richmond 500-kV Substation Uprate.

1 MR. BROWN: Okay. Okay. When we look at
2 an uprate solution, there's multiple different
3 things it could be. Obviously, the most expensive
4 are rebuilding a line. In this case, although I'm
5 not specifically familiar with the scope offhand,
6 generally an uprate in a station is replacement of a
7 limiting component from a current carrying equipment
8 perspective. It could be a wave trap, which is a
9 device that, you know, is used in current limiting
10 or communication-related device that carries
11 current. It could be a smaller-type asset within a
12 station. Generally, the more favorable from a
13 benefit cost perspective or lower cost operates our
14 substation equipment operates.

15 Also relay settings. Surprisingly,
16 sometimes we are restricted purely by settings on
17 protective relays. So by changing those relay
18 settings sometimes in conjunction with replacing a
19 current transformer or a voltage transformer, we can
20 actually uprate the overall rating of the facility
21 which would be the station and the connected lines.

22 COMMISSIONER McKISSICK: Thanks for the
23 education.

24 MR. BROWN: You're welcome.

1 CHAIR MITCHELL: All right. Let me check
2 and see if there are any additional questions for
3 the DEP panel before we let them go.

4 (No response)

5 All right. Well, thank you-all very much
6 for your presentation today. We appreciate your
7 being here with us and the explanations you've
8 provided.

9 MR. BROWN: Thank you.

10 CHAIR MITCHELL: All right. Mr. Jeffries,
11 if you would, we would like a follow-up filing on
12 the TC-7 identifying the projects there.

13 MR. JEFFRIES: We've got those, that
14 noted --

15 CHAIR MITCHELL: Okay.

16 MR. JEFFRIES: -- Chair Mitchell.

17 CHAIR MITCHELL: Thank you, sir. All
18 right. You all may step down. Thank you.

19 MR. BROWN: Thank you.

20 CHAIR MITCHELL: All right. Ms. Cress,
21 it's my understanding CIGFUR II has a witness who
22 you all would like to call.

23 MS. CRESS: Yes, Chair Mitchell. Thank
24 you. And I'll just note at the outset that we only

1 learned moments before this Technical Conference
2 began that we would be the only party making a
3 presentation, but since our witness is here from
4 Missouri, we are going to go ahead with our
5 presentation and we appreciate the opportunity to do
6 so.

7 CHAIR MITCHELL: Okay. Absolutely.

8 MS. CRESS: So with that, I'll turn it
9 over to Bob Stephens with Brubaker and Associates.
10 Thank you.

11 MR. STEPHENS: Good afternoon, Chair. Can
12 you hear me okay?

13 MR. STEPHENS: Yeah.

14 CHAIR MITCHELL: We can hear you.

15 MR. STEPHENS: Good afternoon, Chair
16 Mitchell and Commissioners. I don't know if my --
17 there is my presentation. All right.

18 You're all new to me and I'm new to you.
19 I'm Bob Stephens. I'm with the firm Brubaker and
20 Associates here on behalf of CIGFUR, the -- I'm
21 sorry -- Carolina Industrial Group For Fair Utility
22 Rates.

23 Those are my qualifications. I won't go
24 through them in the interest of time. I'll just

1 note a couple. I've been in the consulting industry
2 regulated -- regulatory consulting and consulting
3 the individual customers on electric rate matters
4 for nearly 25 years. Before that I worked at the
5 Illinois Commerce Commission and before that a
6 utility.

7 I will skip over this page. You know what
8 the mega trends are. We've already covered that.
9 Here, I'd like to talk about what are priorities for
10 CIGFUR. We're talking about billions of dollars of
11 spend here, and it's true that there will need to be
12 additional transmission distribution investments.
13 There's no question about that. But from industrial
14 customers' point of view, it's going to be
15 imperative that we manage the cost of service
16 because right now competitively priced service in
17 North Carolina at a high level of reliability is
18 helping to drive the industrial economy which helps
19 drive the overall economy. So we ask that the cost
20 of service be managed and the rate changes be as
21 gradual as are feasible.

22 We encourage DEP to develop capital
23 projects at least cost considering all options,
24 transmission, production, and distribution, not

NORTH CAROLINA UTILITIES COMMISSION

1 siloing into one. And we've gotten some indication
2 earlier today that they don't necessarily do that in
3 all cases, but we want to encourage as much
4 coordination there as feasible. And we want to
5 encourage capital budget timing such that rate base
6 doesn't grow in leaps and bounds suddenly.

7 DEP has identified billions of dollars'
8 worth of costs here. Approximately three billion by
9 my count based on the presentation. So we want to
10 make sure that capital spend is conducted and
11 deliberate in a gradual way.

12 And then finally, as part of the
13 multi-rate plans, there will be tariff rates
14 proposed and we want to make sure that those are set
15 rationally, that they help encourage conservation
16 among customers by efficient price signals, and that
17 they reflect cost of service.

18 Regarding T&D service quality, it's
19 important that we've heard several options for both
20 supply and demand reliability. We want to make sure
21 that the demand side is exhausted because customers
22 can provide interruptible capacity that can help
23 alleviate some of the stresses on both the
24 transmission and distribution systems.

1 We want to ensure that power quality is
2 maintained and at a least cost. You've heard talk
3 today about voltage stability. For industrial
4 customers, even small or even very momentary changes
5 in voltage can have a detrimental impact. Sag,
6 surges, transient changes generally under voltage
7 that can all affect equipment and production. In
8 fact, voltage sags even momentary can shut down
9 industrial plants. They can damage equipment. And
10 when that happens, you have lost production, you
11 have in some cases the inability to meet customers'
12 needs. So it's very important to maintain adequate
13 voltage stability as well as frequency.

14 And then similarly SAVE and SAFe and CAIDe
15 (spelling uncertain) are all valid measures, but you
16 heard some discussion by Mr. Maley about what's a
17 momentary outage. Momentary are the ones below one
18 minute. For industrial customers harm can happen
19 within a second. So we should consider another
20 measure M-A-I-F-I, MAIFI, Momentary Average
21 Interruption Frequency Index, which is the total of
22 the momentary outages in the year divided by the
23 number of customers.

24 Regarding tariff rates and efficient

1 consumption, we want efficient rates. We want fair
2 rates. For the transmission service, cost should be
3 allocated based on coincident demands. For
4 distribution service at the circuit level,
5 non-coincident demands are typically used taking
6 into account customer density and circuit miles is
7 an important factor as well.

8 When prices are efficient, they provide an
9 economic incentive to customers to conserve. For
10 example, if you set your demand rates too high and
11 your energy rates too low, customers will get the
12 wrong signal thinking that their demands don't cause
13 cost on the system to the extent they do and,
14 likewise, if their energy costs more. The most
15 efficient functioning of a utility is when the
16 prices reflect cost, so the customers can respond
17 accordingly.

18 So I've covered a few things. Here are
19 the key takeaways. The importance of gradualism and
20 avoiding rate shock. We'd like for DEP to be able
21 to show that system reliability benefits exceed the
22 cost of the planned capital -- T&D capital spending.
23 Indications so far are that they do, but we haven't
24 dug into the numbers yet and that will be a part of

1 the filing once made.

2 Delivery voltage should be aligned with
3 embedded cost. If you're taking service at 230-kV,
4 you don't use any distribution assets and,
5 therefore, you shouldn't be charged cost of the
6 distribution system, including these distribution
7 improvements.

8 DEP covered the fact that the federal
9 funds are being used. We encourage the Commission
10 to make sure those funds are maximized.

11 And then finally, look at things beyond
12 just SAVe and SAFe for measures of reliability to
13 get to the important momentary interruptions as
14 well.

15 We look forward to digging into DEP's
16 filing once it's made. And with that, if you have
17 any questions, I'll do my best to answer.

18 CHAIR MITCHELL: All right. Thank you,
19 sir. Let me check in with Commissioners to see if
20 there are questions for you. Any questions from
21 Commissioners Brown-Bland, Duffley, or Hughes?

22 (No response)

23 I'm not seeing any. Well, thank you very
24 much, sir, for your comments today. You may step

1 down.

2 MR. STEPHENS: Thank you.

3 CHAIR MITCHELL: All right. And with
4 that, we've come to the end of our day. Thank you,
5 again, to all the presenters and for sharing this
6 information with us. And with that, we'll be
7 adjourned. Thank you.

8 (The technical conference was adjourned)
